EXECUTIVE SUMMARY

The 2001 National Pollutant Discharge Elimination System (NPDES) marine monitoring program for the El Segundo and Scattergood Generating Stations was conducted in accordance with specifications set forth by the California Regional Water Quality Control Board, Los Angeles Region (LARWQCB) in NPDES Permit Nos. CA0001147 and CA0000370, respectively. The 2001 sampling included physical and chemical monitoring of the receiving waters and sediments, and biological monitoring of infaunal assemblages and mussels. Fish and macroinvertebrate impingement studies were also conducted periodically throughout the year. Results of the 2001 sampling surveys were compared among stations and with previous studies to determine if the beneficial uses of the receiving waters continue to be protected.

The Scattergood Generating Station is owned and operated by the Los Angeles Department of Water and Power (LADWP). The El Segundo Generating Station, formerly owned by Southern California Edison Company (SCE), was purchased by El Segundo Power L.L.C. on 4 April 1998.

WATER COLUMN MONITORING

Water quality measurements in 2001 indicated that there was no detectable thermal elevation in the study area during either the winter or summer survey. Thermal differences noted between tides were probably due to solar insolation warming the surface layers. All noted temperature differentials between stations were minor or directly related to the depth of the station. Elevations of less than 1.5°C were noted at all stations between tides in winter; these appear to have been the result of insolation heating and then transport offshore on the tides. Only minor variations in temperature, dissolved oxygen (DO), pH, and salinity were detected. During the summer, surface temperatures were typically higher than in winter, with seasonal stratification apparent throughout the study area, including a cold water mass, which usually indicates upwelling, detected at some stations. All temperature, DO, pH, and salinity values were within the normal ranges for the area and seasons. Water quality measurements indicated that the cooling water discharges from the El Segundo and Scattergood Generating Stations did not have an adverse effect on receiving waters in the study area.

SEDIMENT MONITORING

Sediment Grain Size

In 2001, sediments in the study area consisted primarily of sand (average 89%) with a mean grain size of 2.46 phi (fine sand). Sediments were coarsest at offshore Station B5, upcoast of the Scattergood and El Segundo discharge structures, and finest at inshore Station B1, also upcoast of the discharge structures. At Station B5, mean grain size was more than five times the mean grain size at the other offshore stations. Sediments at Station B5 appeared to be composed primarily of relict red sands, which are known to occur at several nearshore locations in Santa Monica Bay. Sediment composition and distribution in the study area are likely affected by natural causes unrelated to the operation of the generating stations. No spatial patterns were apparent that would suggest effects from the Scattergood or El Segundo Generating Stations.

Sediment Chemistry

In 2001, sediment concentrations of all metals were highest at inshore Stations B1 and B2. Slightly higher concentrations of metals at Station B2 corresponded with higher amounts of fine sediments (silt and clay) at that station. Lowest concentrations of chromium, copper, and zinc were detected at nearshore Station B3, and lowest nickel concentration was recorded at offshore Station B5. Sediment metal concentrations in the study area were within the range found in sediments throughout the Southern California Bight and continue to be below levels determined to be potentially toxic to benthic organisms. No effects from the operation of the El Segundo and Scattergood Generating Stations were detected from the 2001 sampling.

MUSSEL BIOACCUMULATION

Analysis of metal levels in mussels near the El Segundo and Scattergood Generating Station in 2001 indicated bioaccumulation of metals was not appreciable. Tissue concentrations of copper in mussel tissue from the El Segundo Generating Station were lower than in 2000 or 1999, when copper levels were inexplicably high. Zinc concentrations from mussels collected in the same area were similar to values previously recorded since 1990. Copper and zinc concentrations in mussel tissue from Scattergood Generating Station were also similar to previously recorded values in the study area. Chromium and nickel have not been detected since 1990. Metal levels were not elevated in comparison to those found at other locations in the Southern California Bight.

BIOLOGICAL MONITORING

Benthic Infauna

The benthic infauna community sampled in 2001 was similar in composition to that of previous years. Species richness averaged 58 species per station, the second highest ever recorded for the study area. Abundance averaged 486 individuals per station (12,138 individuals/m²). More than 38% of the abundance consisted of only one species, the polychaete worm *Apoprionospio pygmaea*, which has been a community dominant in all previous surveys. Abundance was greatest nearshore, while species richness and diversity were greater offshore than nearshore. This pattern is probably due to the finer, more poorly sorted sediments and calmer environment offshore. At Station B5, offshore and furthest upcoast, relict sands were encountered which appeared to alter the community by reducing the abundance of tube-dwelling worms, such as *A. pygmaea*. The abundance or species composition of the infaunal community did not appear to be influenced by the operation of the El Segundo or Scattergood Generating Stations.

Impingement

There were noticeable differences between the El Segundo and Scattergood Generating Stations in the species of fish and macroinvertebrates impinged in 2000. Some of these differences are likely due to plant operations, such as flow rates and heat treatment schedules, and some are due to drifting or schooling species encountering the intake structures on a random basis. All of the species common to both El Segundo and Scattergood were typical in the offshore habitat. The occurrence of these species throughout the Southern California Bight, and their continued abundance and high species diversity at both generating stations, indicated that operation of the El Segundo and Scattergood Generating Stations is not having an appreciable adverse effect on the diverse fish and macroinvertebrate populations in the study area.

CONCLUSION

The overall results of the 2001 NPDES monitoring program indicated that operation of the El Segundo and Scattergood Generating Stations had no detectable adverse effects on the beneficial uses of the receiving waters.

INTRODUCTION

This report presents and discusses the results of the 2001 receiving water monitoring studies conducted for the El Segundo and Scattergood Generating Stations. The 2001 monitoring program was conducted in accordance with specifications set forth in National Pollutant Discharge Elimination System (NPDES) Monitoring and Reporting Program No. 4667 (Permit No. CA0001147) issued for the El Segundo Generating Station by the California Regional Water Quality Control Board, Los Angeles Region (LARWQCB) on 29 June 2000, and NPDES Monitoring and Reporting Program No. 1886 (Permit No. CA0000370) issued for the Scattergood Generating Station by the LARWQCB on 29 June 2000 (Appendix A). Results of the 2001 surveys were compared among stations and with past physical oceanographic and biological studies to determine what effects, if any, the generating station discharge is having on the marine environment, and if the beneficial uses of the receiving waters are being protected. Sampling included physical and chemical monitoring of the receiving waters and sediments, mussel bioaccumulation, and biological monitoring of infaunal assemblages. Fish and macroinvertebrate impingement studies were also conducted periodically throughout the year.

The Scattergood Generating Station is owned and operated by the Los Angeles Department of Water and Power (LADWP). The El Segundo Generating Station is owned and operated by El Segundo Power L.L.C.

DESCRIPTION OF GENERATING STATIONS

El Segundo Generating Station

The El Segundo Generating Station is located at the south western boundary of the City of El Segundo. It consists of four fossil-fuel, steam-electric generating units. Units 1 & 2 are rated at 175 Megawatts (Mw) each and Units 3 & 4 at 335 Mw each. The total station rating is 1,020 Mw; however, the plant operated at 42.9% of total capacity in 2001 (Sanchez 2001, pers. comm.).

Seawater for cooling is supplied to Units 1 & 2 via a 10-foot (ft) (3.0-meter [m]) inside diameter (ID) concrete conduit which extends approximately 790 m offshore to a depth of -30 ft Mean Lower Low Water (MLLW). Approximately 144,000 gallons per minute (gpm) are supplied to the units through a screening structure at the plant end of the intake conduit. The screens remove trash, algae, and marine organisms which enter with the cooling water. After passing the screens, the cooling water is pumped to each of two steam condensers, one per turbine. The water temperature is increased 12.2°C when the units are operated at full capacity. The heated water is discharged through a 10-ft-ID conduit, which terminates approximately 1,900-ft (500-m) offshore at a water depth of -26 ft MLLW.

The cooling water system for Units 3 & 4 is separate from Units 1 & 2 but is essentially the same. Units 3 & 4 characteristics are: 12-ft (3.6-m) ID intake and discharge conduits, extending 2,600-ft (800-m) and 2,100-ft (640-m) offshore at -30 ft MLLW respectively; the cooling water flow is 295,000 gpm; and temperature rise across the condensers at full load is 12.2°C.

During the winter sampling on 28 March 2001, four circulating pumps were operating at Units 1 & 2 producing a flow of 207.4 million gallons per day (mgd). The ambient temperature was 16.4°C at the intake and 29.8°C at the discharge, 13.4°C above ambient. At Units 3 & 4, two circulating pumps discharged 199.3 mgd with an intake temperature of 19.9°C and discharge temperature of 19.7°C, 0.2°C below the intake temperature. During summer sampling on 20 September 2001, 207.4 mgd was discharged by four circulating pumps at Units 1 & 2 with 398.6 mgd discharged by four circulating pumps at Units 3 & 4. The discharge temperature was 40.1°C at Units 1 & 2, 19.1°C above ambient, and 27.4°C at Units 3 & 4, 6.8°C above ambient (Sanchez 2001, pers. comm.).

Scattergood Generating Station

The Los Angeles Department of Water and Power's Scattergood Generating Station is located in the City of Los Angeles at the western boundary of the City of El Segundo, approximately one-half mile north of the El Segundo Generating Station. It is comprised of three fossil-fueled, steam-electric generating units. Units 1 & 2 are rated at 185 Mw each and Unit 3 at 460 Mw. Units 1 & 2 have been on-line since 1958-1959 and Unit 3 since 1974. The total capacity of the plant is 830 Mw; however, the plant operated at 21.3% of capacity in 2001 (Mofidi 2001, pers. comm.).

Cooling water is drawn from Santa Monica Bay, at a maximum rate of 344,000 gpm, through a single 12-ft (3.6-m) ID conduit, which extends approximately 500 m offshore. Seawater enters the system through a 17.5-ft (5.3-m) ID vertical riser. The flow is directed horizontally to the inlet conduit through a 32.5-ft (9.9-m) diameter velocity cap which is suspended 5 ft (1.5-m) above the vertical riser. Seawater is drawn from near mid-depth at an elevation of -15 ft MLLW; the seafloor at this location is approximately -30 ft MLLW. Water enters the plant approximately 150 m inland via a walled forebay containing a screen array and pumping chamber. The design temperature increase for Units 1 & 2 is 10°C; Unit 3 operates at a temperature increase of 7.8°C.

Cooling water is discharged through a single 12-ft (3.6-m) ID conduit that runs parallel to the intake conduit. The discharge riser is also 17.5 ft (5.3-m) ID and has a lip at -15 ft MLLW. The discharge riser is located approximately 365 m offshore from the mean high tide line. Depth of the seafloor at this location is approximately -27 ft MLLW.

During the winter sampling on 28 March 2001, 112 mgd of cooling water were discharged by two circulating pumps. The discharge temperature was 26.7°C, 6.7°C above ambient. On 20 September 2001, seven circulators pumped 335 mgd of cooling water at a discharge temperature of 26.1°C, 5.0°C above the ambient intake temperature of 21.1°C (Mofidi 2001, pers. comm.).

DESCRIPTION OF STUDY AREA

Location

The study area is located in Santa Monica Bay between latitudes 33°56'N and 33°52'N; and longitudes 118°25'W and 118°28'W (Figure 1). The Chevron USA - El Segundo Refinery is located between the two generating stations. The Hyperion Treatment Plant, with its deep-water discharge, is approximately 450 m upcoast of the Scattergood Generating Station. Farther north is Marina del Rey Harbor and the mouth of Ballona Creek. Manhattan Beach Pier and the southernmost set of survey stations are downcoast of both generating stations.

Physiography

The general orientation of the coastline between Point Conception and the Mexican border is from northwest to southeast. The continental margin has been slowly emerging over geological time, resulting in a predominantly cliffed coastline which is broken by plains in the vicinity of Oxnard-Ventura, Los Angeles, and San Diego. Most of the coastal region drains via short streams which flow only during rain storms. However, only a small part of the storm drainage reaches the ocean directly; most is impounded by dams or diverted for other uses.

The eight islands offshore southern California influence water circulation and oceanographic characteristics along the mainland coast. The mainland shelf is narrow along the coast, ranging from less than 1.6 to more than 15 kilometers (km) wide, and averaging approximately 7 km. Seaward of the shelf is an irregular, geologically complex region known as the continental borderland, comprising basins and ridges which extend from near the surface to depths in excess of 2,400 m.

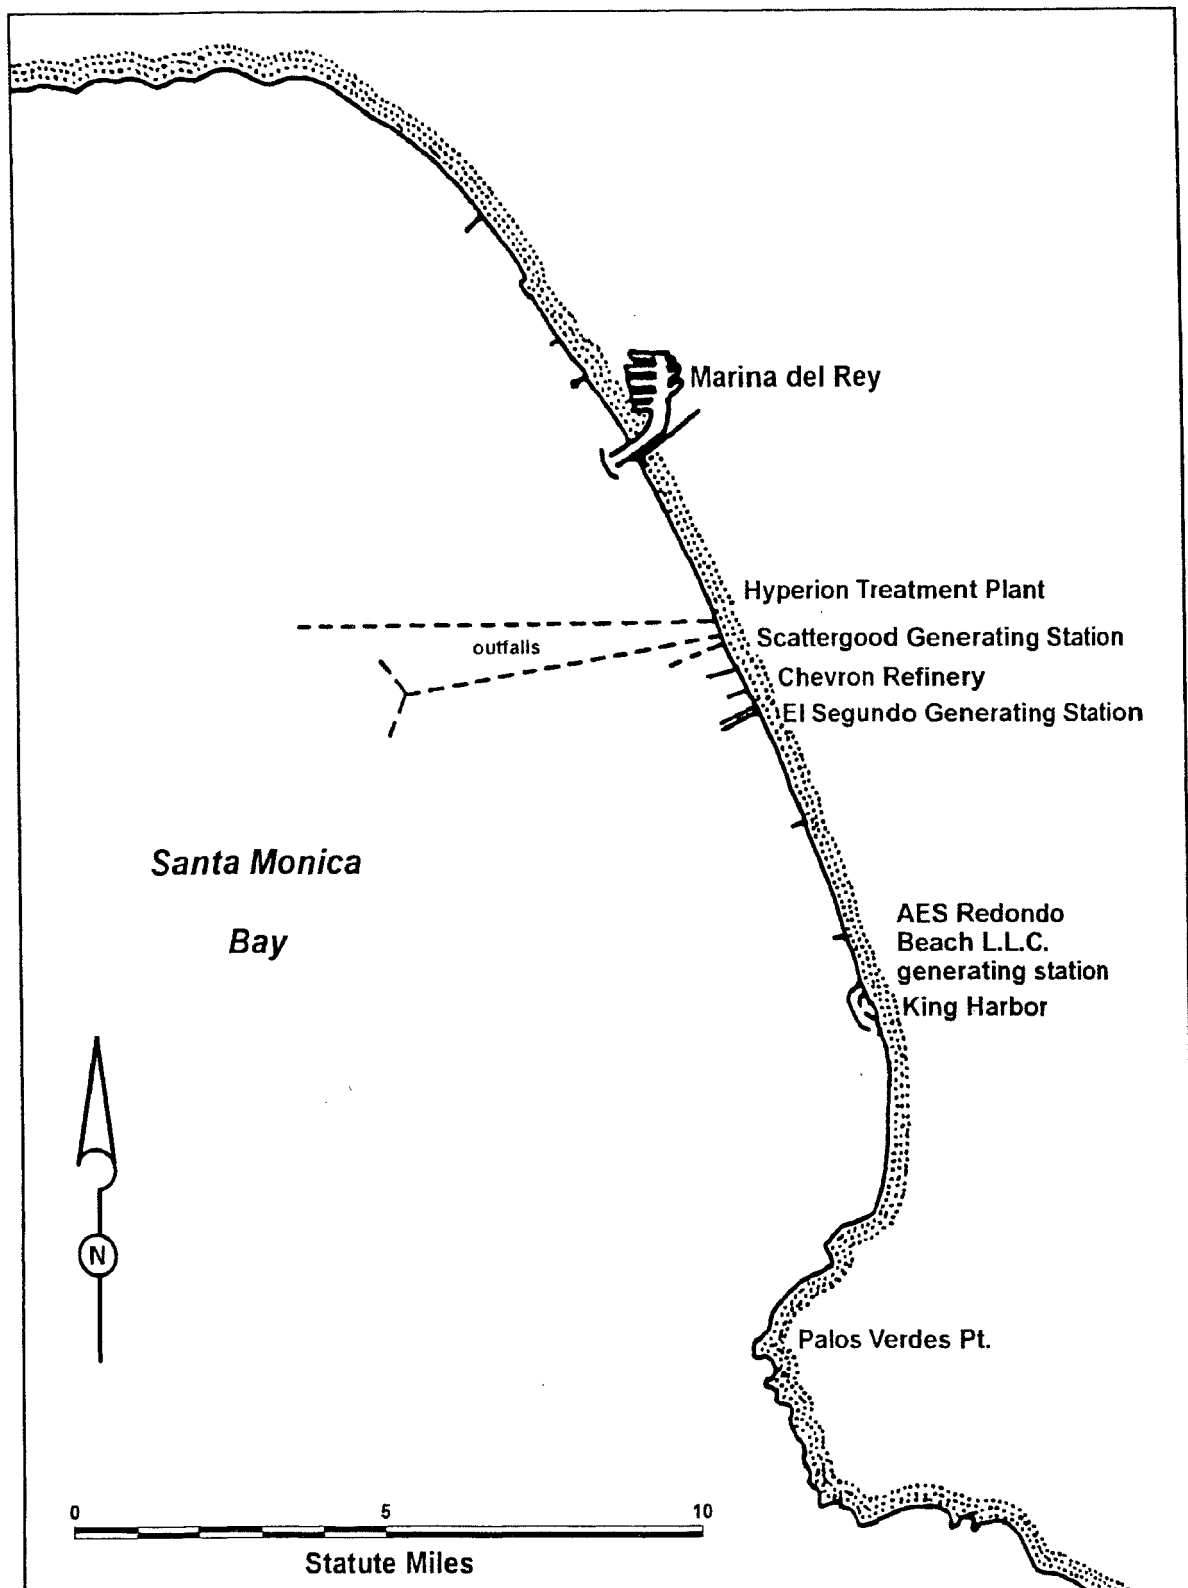

Figure 1. Location of the study area. El Segundo and Scattergood Generating Stations, NPDES 2001.

Oceanographic conditions in the study area are largely a function of offshore water masses, but these are modified by local conditions, especially local submarine topography. Santa Monica Bay is characterized by a gently sloping (about 0.5°) continental shelf. At water depths of about 80 m the shelf steepens as it approaches Santa Monica Basin (Terry et al. 1956). Within the bay the continental shelf ranges in width from a few hundred meters to about 19 km, forming a large central plateau which is dissected by submarine canyons.

Santa Monica Submarine Canyon comes to within 11 km of shore, offshore at Ballona Creek and the head of Redondo Submarine Canyon comes to within a few hundred meters of King Harbor in Redondo Beach. The shelf is broadest in the vicinity of the study area where the El Segundo and Scattergood Generating Stations discharge. Submarine canyons often cause anomalies in current direction and velocity; they may also enhance the transport of bottom water and act as migratory corridors for fish and invertebrates. In 1969, the predominant flow in Redondo Submarine Canyon was up-canyon, at an average speed of about 2.5 centimeters/second (cm/s) (Shepard and Marshall 1973).

Prior to development, the coast between Santa Monica and the Palos Verdes Peninsula consisted primarily of sand dunes, although wetlands were present adjacent to Ballona Creek. At present, about 50% of the shore comprises sandy beaches. Offshore the seafloor is composed largely of unconsolidated sediments which are generally finer with increasing distance from shore. Most nearshore sediments are olive green sands which form an elongate bed off Manhattan Beach and a large patch on the central plateau (Terry et al. 1956). Silty sand is found at mid-depths over much of the central plateau. Clay was a minor sediment constituent in the 1950s, but was more common in the 1970s (Bascom 1978).

Reduced wave intensity in summer allows sand and finer materials to accumulate nearshore; in winter, storms move them offshore to deep water (Grant and Shepard 1939). Nearshore sands typically move parallel to shore by longshore drift and may be transported into the heads of submarine canyons. Sand from the study area is expected to move southward into Redondo Submarine Canyon. Dikes, groins, and jetties have been constructed to interfere with littoral drift to aid in sand retention. In addition, beach nourishment, whereby sand is transported to the beach, is practiced. Since the Ballona Creek drainage was channelized in the 1930s, there has been little sediment input from the coastal plain; the major source of sand is now via runoff from the Santa Monica Mountains and the Santa Clara River (MBC 1988). Sediment moves downcoast from the Santa Clara River, around Point Dume, and into the northern portion of Santa Monica Bay during years of high runoff.

Climate

Southern California lies in a climatic regime broadly defined as Mediterranean, which is characterized by short, mild winters and warm, dry summers. Long-term annual precipitation near the coast averages about 46 cm, of which 90% occurs between November and April. Sea breezes are caused by differential heating between land and sea. During the summer, these breezes combine with the prevailing winds that blow out of the northwest to produce strong onshore winds. They typically start around noon and may continue through late afternoon, with speeds reaching 40 km per hour. In late fall and winter, reverse pressure systems frequently develop, causing coastal offshore winds from the southeast from November through February, typically between 1300 and 2000 hrs. Monthly mean air temperatures along the coast range from 8.3°C in winter to 20.6°C in summer, with the minimum dropping slightly below freezing and the maximum rising above 37°C.

Currents

Water in the northern Pacific Ocean is driven eastward by prevailing westerly winds until it impinges on the western coast of North America, where it divides to flow both north and south. The southern component is the California Current, a diffuse and meandering water mass which generally flows to the southeast (Jones 1971). No fixed western boundary to this current is defined; more than 90% of the bulk water transport is within 725 km of the California coast.

South of Point Conception, the California Current diverges; one branch turns northward and flows inshore of the Channel Islands as the Southern California Countercurrent (Jones 1971).

Figure 2. Surface circulation in the Southern California Bight (from Jones 1971). El Segundo and Scattergood Generating Stations NPDES, 2001.

Surface speed in the countercurrent ranges from 5 to 10 cm/s. The general flow is complicated by small eddies around the Channel Islands and fluctuates seasonally, being well developed in summer and autumn, and weak or even absent in winter and spring. Generalized surface water circulation off southern California is shown in Figure 2. Currents near the coast are strongly influenced by a combination of wind, tide, and topography. When wind-driven currents are superimposed on the tidal motion, a strong diurnal component is usually apparent. Therefore, short-term observations of currents near the coast may often vary considerably in both direction and speed.

Water generally enters Santa Monica Bay from the south and moves in a slow counterclockwise eddy. However, during winter a clockwise gyre may develop, with longshore flow of 2 cm/s (SCCWRP 1973, Hendricks 1980). Recent studies suggest that the clockwise gyre may be the dominant pattern on the shelf and that it reverses for a few days at a time due to tidal action. Tidal currents in Santa Monica Bay were slowest at the

head of Redondo Submarine Canyon and greatest over the central parts of the broad shelf (Allan Hancock Foundation 1965).

Tides

Tides along the California coast are mixed semi-diurnal, with two unequal highs and two unequal lows during each 25-hour (hr) period. In the eastern North Pacific Ocean, the tide wave rotates in a counterclockwise direction. As a result, flood tide currents flow upcoast and ebb tide currents flow downcoast.

Upwelling

The predominantly northwesterly winds along the California coast are responsible for large-scale upwelling. From about February to October these winds induce offshore movement of surface water, which is replaced by the upwelling of deeper ocean waters near the coast. The upwelled water is colder, more saline, lower in oxygen, and higher in nutrient concentrations than surface waters. Thus, upwelling not only alters the physical properties of the surface waters, but also affects biological productivity by providing nutrients for the surface phytoplankton.

RECEIVING WATER CHARACTERISTICS

Water quality at El Segundo and Scattergood Generating Stations is affected by hydrology, currents, storm water runoff, industrial discharges, and ship traffic. In addition, climatological parameters such as solar radiation, humidity, and wind influence the condition of the receiving water.

The capacity of the marine environment to assimilate heated effluent depends on its ability to dilute and disperse the thermal discharge. The extent to which these functions are accomplished depends on the quantity and temperature of the thermal effluent relative to normal ocean temperature, ocean current patterns, and dispersion characteristics of the receiving waters. The following discussion focuses on natural ocean temperatures along the southern California coast and in Santa Monica Bay and addresses other physical and chemical oceanographic characteristics that influence the local marine biota.

Temperature

Natural water temperatures fluctuate throughout the year in response to seasonal and diurnal variations in currents, meteorological conditions such as wind, air temperature, relative humidity, and cloud cover, and other parameters such as ocean waves and turbulence. Natural temperature is defined by the California State Water Resources Control Board as "the temperature of the receiving water at locations, depths, and times which represent conditions unaffected by any elevated temperature waste discharge."

On the average natural surface water temperatures may be expected to vary diurnally 1°C to 2°C in summer and 0.3°C to 1°C in winter (EQA/MBC 1973). Factors which contribute to rapid daytime warming of the sea surface include weak winds, clear skies, and warm air temperatures. Conversely, overcast skies, moderate air temperatures, and the mixing of surface waters by winds and waves limit the daily warming. Natural surface water temperatures in Santa Monica Bay range from 11.7°C to 22.2°C annually (EQA/MBC 1973).

When there is a large difference between surface and bottom water temperatures, a steep temperature gradient between adjacent water layers of different temperatures (a thermocline) may develop. Natural thermoclines are formed when absorption of solar radiation elevates the temperature of surface water which then remains separated from the subsurface layer. Artificial thermoclines may result when warm water from a thermal discharge overlies cooler receiving waters. Off southern California, a reasonably sharp natural thermocline normally develops during the summer months; winter thermoclines are weakly defined.

Salinity

Salinity is a measure of the concentration of dissolved salts and is relatively constant in the open ocean. In coastal environments it fluctuates as a result of the introduction of freshwater runoff, direct rainfall, and evaporation. Salinities in Santa Monica Bay are relatively uniform, ranging from 33.0 to 34.0 parts per thousand (ppt) (Allan Hancock Foundation 1965).

Density

Seawater density varies inversely with temperature and directly with salinity. Water temperature is the major factor influencing density stratification in southern California since salinity is relatively uniform. As a result, density gradients are most pronounced in spring and summer. Thermoclines are often present during these parts of the year.

Dissolved Oxygen

Dissolved oxygen (DO) is utilized by aquatic plants and animals for respiration. It is replenished by gaseous exchange with the atmosphere and as a by-product of photosynthesis. Concentrations of DO in the surface waters of Santa Monica Bay range from approximately 5 to 12 milligrams per liter (mg/l) (Allan Hancock Foundation 1965). High DO values can result from increased photosynthetic activity and low values result from the decomposition of organic matter and mixing of surface waters with oxygen-poor subsurface waters.

Hydrogen Ion Concentration

The hydrogen ion concentration (pH) in the Southern California Bight varies narrowly around a mean of approximately 8.0 and decreases slightly with depth. Normal pH values in Santa Monica Bay range between 8.0 and 8.6 (Allan Hancock Foundation 1965).

BENEFICIAL USES OF RECEIVING WATERS

The California Regional Water Quality Control Board (1994) enumerated 10 beneficial uses of coastal and tidal waters in the nearshore zone of the Pacific Ocean. Of these, nine were specifically identified with the El Segundo-Scattergood area:

Industrial Service Supply

Uses which do not depend primarily on water quality such as mining, cooling water, hydraulic conveyance, gravel washing, fire protection, and oil well repressurization.

Water Contact Recreation

Includes all recreational uses involving body contact with water, such as swimming, wading, water skiing, skin diving, surfing, sportfishing, use in therapeutic spas, or other uses where ingestion of the water is reasonably possible.

Non-contact Water Recreation

Recreational uses which involve the presence of water, but do not necessarily require body contact, such as picnicking, sunbathing, hiking, beachcombing, camping, pleasure boating, tide pool and marine life study, hunting, and general aesthetic enjoyment.

Ocean Commercial and Sportfishing

Includes the commercial collection of fish and shellfish, including those collected for bait, plus sportfishing in the ocean, bays, estuaries, and similar non-freshwater areas.

Marine Habitat

Provides for the preservation of the marine ecosystem, including the propagation and sustenance of fish, shellfish, marine mammals, waterfowl, and marine vegetation.

Preservation of Rare and Endangered Species

Provides an aquatic habitat necessary, at least in part, for the survival of certain species established as being rare or endangered.

Navigation

Includes commercial and ocean shipping, and military (naval) operation.

Shellfish Harvesting

The collection of shellfish such as clams, oysters, abalone, shrimp, crab, and lobster for sport or commercial purposes.

Fish Spawning

Provides high quality aquatic habitat especially suitable for fish spawning.

MATERIALS AND METHODS**SCOPE OF THE MONITORING PROGRAM**

The 2001 monitoring program for the El Segundo and Scattergood Generating Stations was conducted by MBC Applied Environmental Sciences (MBC) in accordance with specifications set forth in the NPDES Monitoring and Reporting Programs (Appendix A). The monitoring program included winter and summer water column profiling, summer sediment sampling for grain size and chemistry, mussel sampling for bioaccumulation, summer biological sampling for benthic infauna, and periodic impingement sampling for fish and macroinvertebrates.

STATION LOCATIONS

The locations of the monitoring stations are described in Appendix A and shown in Figure 3. The 2001 monitoring program included 12 receiving water (RW) water quality stations and eight sediment and benthic infauna (B) stations.

WATER COLUMN MONITORING

Temperature (°C), dissolved oxygen (DO), hydrogen ion concentration (pH), and salinity (ppt) were continuously measured throughout the water column during the winter and summer surveys. Sampling was conducted on both flood and ebb tides at each of the 12 receiving water monitoring stations (Figure 3). Data were obtained *in situ* using an SBE 9/17 CTD water quality profiling system (Sea-Bird), and averaged at 1.0 m intervals. In the field, the data were transferred from the Sea-Bird to floppy disk for storage. In the laboratory, data were processed using Sea-Bird proprietary software (SeaSoft ver. 4.21). The resulting information was imported into Microsoft Excel spreadsheets for further reduction and analysis.

SEDIMENT MONITORING

Sediment samples for grain size and metal chemical analyses were collected during the summer survey at eight benthic stations (Stations B1 - B8) by biologist-divers. Grain size samples were collected using a 15-cm-long, 3.5-cm-diameter, plastic core tube. Sediment samples were collected at the same time infauna samples were taken, and were transferred to jars or plastic bags for later laboratory analysis.

Sediment Grain Size

The size distributions of sediment particles were determined using two techniques: laser light diffraction to measure the amount and patterns of light scattered by a particle's surface for the sand/silt/clay fraction, and standard sieving for the gravel fraction. Laboratory data from the two

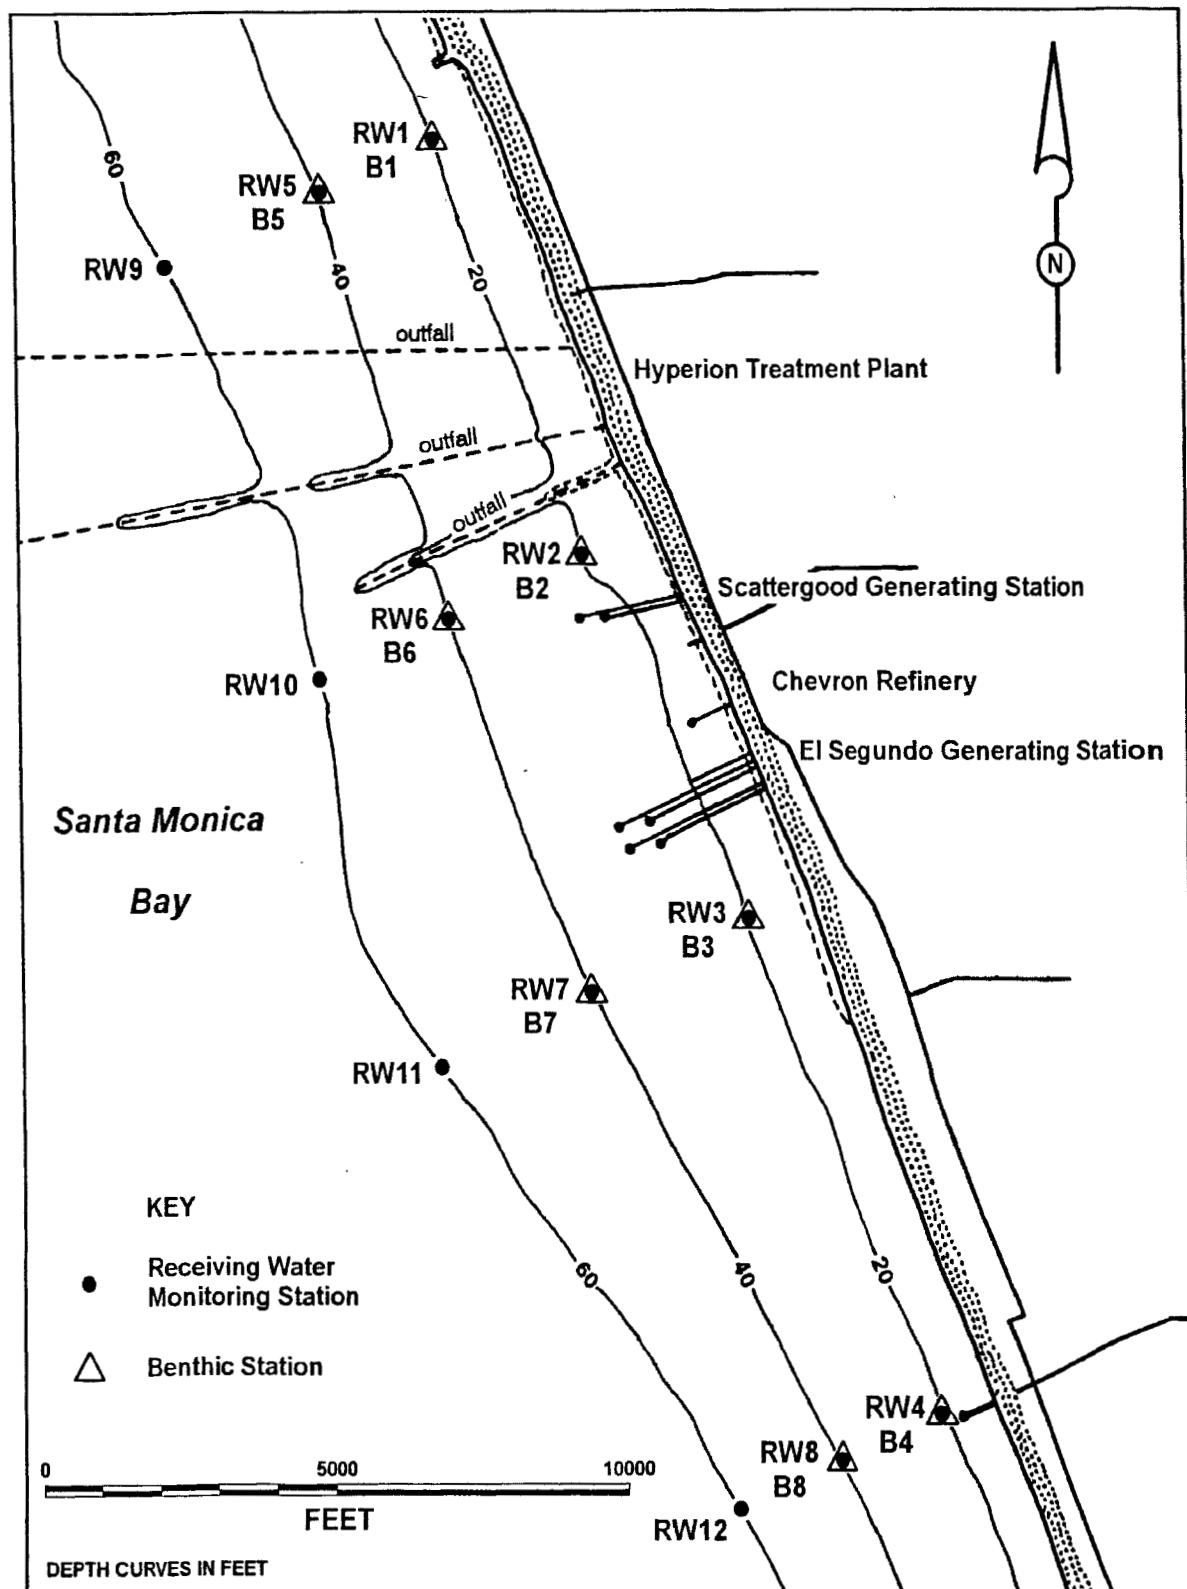

Figure 3. Location of the monitoring stations. El Segundo and Scattergood Generating Stations NPDES, 2001.

methods were combined and presented in tabular format. Resulting analyses include mean and median grain size, standard deviation of the grain size, sorting, skewness, and kurtosis. Data were plotted as size-distribution curves. Additional details are provided in Appendix B.

Sediment Chemistry

Sediment cores collected for chemical analyses were placed on ice in the field and maintained at approximately 4°C until laboratory procedures began. Sediments were analyzed for total percent solids and four metals: chromium, copper, nickel, and zinc. Environmental Protection Agency (EPA) method 160.3 was used to determine percent solids and EPA method 6010 was used for metals.

MUSSEL BIOACCUMULATION

Bay mussels (*Mytilus edulis*) were collected near the discharges by biologist-divers for bioaccumulation monitoring. One set of 45 mussels with shell lengths ranging from 47 to 57 millimeters (mm) and averaging 51.4 mm at Scattergood Generating Station and two sets of 45 mussels with shell lengths ranging from 50 to 76 mm and averaging 61.1 mm at El Segundo Generating Station, were divided into groups (replicates) of 15 mussels each and processed according to methods used in the California Mussel Watch (Appendix A and SWRCB 1986). Soft tissue from the mussels was analyzed for copper, chromium, nickel, and zinc. Results were compared to levels found in other mussel watch programs, including resident bay mussels from two reference sites, the west end of Catalina and the Manhattan Beach Pier, which were collected and analyzed concurrently with another generating station's NPDES monitoring program.

BIOLOGICAL MONITORING

The biological monitoring program consisted of benthic infauna sampling by biologists using diver-operated box corers at eight stations (Stations B1 - B8) during the summer survey. Sampling fish and macroinvertebrate populations from heat treatment impingement operations were conducted at the screenwells of the El Segundo and Scattergood Generating Stations.

Benthic Infauna

Infaunal sampling was conducted at the eight benthic stations (Figure 3), using a hand-held, diver-operated box corer (Figure 4) which collects a bottom sample of 10 cm x 10 cm x 10 cm for a total sample volume of 1.0 liter (l). The box corer is pushed into the sediment and a closing blade is swung across the mouth of the box. The core is then withdrawn from the sediment and sealed by a neoprene lid for transport to the surface.

Samples were washed in the field using a 0.5 mm stainless-steel mesh screen, labeled, and fixed in buffered 10% formalin-seawater. In the laboratory, samples were re-screened through a 0.25 mm sieve, transferred to 70% isopropyl alcohol, sorted to major taxonomic groups, identified to the lowest practical taxonomic level, and counted. Representative specimens were added to MBC's reference collection.

Figure 4. Diver-operated box corer used to collect infaunal samples. El Segundo and Scattergood Generating Stations NPDES, 2001.

Following identification, the weight of organisms in the major taxonomic groups in each replicate was obtained. Specimens were placed on small, pre-weighed mesh screens which had been submersed in 70% isopropyl alcohol, blotted on a paper towel, and air-dried for five minutes. Total wet weight minus screen tare weight provided the wet weight of the organisms. Large organisms were weighed separately.

Impingement

Impingement sampling is conducted during representative periods of normal operation and during all heat treatment procedures to obtain an estimate of total impingement for the year. A normal operation survey is defined as a sample of all fish and macroinvertebrates entrained by water flow into the generating station intake and subsequently impinged onto traveling screens during a 24-hr period with all circulating pumps operating, if possible. The number of operational days is usually less than 365 because of plant maintenance downtime and seasonal fluctuations in the demand for electricity, which may result in decreased water flow into the power plant. Normal operation abundance and biomass for the year are estimated by extrapolating the monitored abundance and biomass based on the percentage of the annual flow into the plant on the days sampled. Exceptions to this method are made where such extrapolations would result in exaggerated counts for species that typically occur in low abundance.

A heat treatment is an operational procedure designed to eliminate mussels, barnacles, and other fouling organisms, which grow in and occlude the generating station conduits. During a heat treatment, heated effluent water from the discharge conduit is re-entrained via cross-connecting tunnels to the intake conduit until the water temperature rises to approximately 40.5°C in the screenwells. This temperature is maintained for a period of at least one hour during which time all mussels, barnacles, and incidental fish and invertebrates living within the intake conduit and forebay succumb to the heated water. All material is subsequently impinged onto the traveling screens and removed from the forebay. The fish and macroinvertebrates are then separated from incidental debris, sorted by species, identified, and counted. Fish are measured in millimeters to either standard length (SL), total length (TL), or disc width (DW), as appropriate, and examined for external parasites, anatomical anomalies, and other abnormalities. Aggregate weights are taken by species for both fish and macroinvertebrates. Unusual specimens and those of uncertain identity are preserved in 10% formalin-seawater and returned to the laboratory for positive species determination and, if warranted, retention in the MBC collection of voucher species. Data are collected for each heat treatment survey and combined with the estimated normal operation data to determine the total impingement loss for the year.

STATISTICAL ANALYSES

Summary statistics developed from the biological data included the number of individuals (expressed as both number per grab and density), number of species and Shannon-Wiener (Shannon and Weaver 1962) species diversity (H') index. The diversity equation is as follows:

Shannon-Wiener

$$H' = - \sum_{j=1}^S \frac{n_j}{N} \ln \frac{n_j}{N}$$

where:

- H' = species diversity
- n_j = number of individuals in the j^{th} species
- S = total number of species
- N = total number of individuals
- j = each species

Data from infaunal coring collections were subjected to log transformations (when necessary) and classified (clustered) using the SYSTAT (SYSTAT ver. 5.0, Systat, Inc., Evanston, IL) clustering module (Wilkinson 1986). Cluster analysis provides a graphic representation of the relationship between species, their individual abundance, and spatial occurrence among the stations sampled. In theory, if physical conditions were identical at all stations, the biological community would be expected to be identical as well. In practice this is never the case, but it is expected that the characteristics of adjacent stations would be more similar than those distant from one another. The dendrogram shows graphically the degree of similarity (and dissimilarity) between observed characteristics and the expected average. The two-way analysis utilized in this study illustrates groupings of species and stations, as well as their relative abundance, expressed as a percent of the overall mean. Two classification analyses are performed on each set; in one (normal analysis) the sites are grouped on the basis of the species which occurred in each, and in the other (inverse analysis) the species are grouped according to their distribution among the sites. Each analysis involves three steps. The first is the calculation of an inter-entity distance (dissimilarity) matrix using Euclidean distance (Clifford and Stephenson 1975) as the measure of dissimilarity.

Clifford and Stephenson

$$D = \left[\sum_1^n (x_1 - x_2)^2 \right]^{1/2}$$

where:

D	=	Euclidean distance between two entities
x ₁	=	score for one entity
x ₂	=	score for other entity
n	=	number of attributes

The second procedure, referred to as sorting, clusters the entities into a dendrogram based on their dissimilarity. The group average sorting strategy is used in construction of the dendrogram (Boesch 1977). In step three, the dendrograms from both the site and species classifications are combined into a two-way coincidence table. The relative abundance values of each species are replaced by symbols (Smith 1976) and entered into the table. In the event of extreme high abundance of a single species, abundance data are transformed using a natural log transformation [ln(x)].

DETECTION LIMITS

Detection limits (DL) used in reporting chemistry results are interpreted as the smallest amount of a given analyte that can be measured above the random noise inherent in any analytical tool. Thus, any value below the DL cannot be considered a reliable estimate of analyte concentration. Therefore, where a test for a given analyte results in a level below the DL, a "none detected" (ND) value has been assigned. The complication of what numerical value to substitute for ND in statistical calculations is addressed by EPA (1989, Section 5.3.3). When values for a given analyte are ND for all stations, then means and standard deviations will also be considered ND. However, when an analyte is detected at some stations and not at others, statistical calculations can be made by substituting ND values with either (a) zero, (b) one-half the average detection limit, or (c) the average detection limit (EPA 1989). Determining which substitution to use is based on whether or not substantial information exists to support the historical presence or absence of a given analyte at the station location. Since chemistry analyses have repeatedly resulted in ND values at the same stations through past surveys, ND values have been replaced with zeros in performing statistical calculations. This decision is also based on the fact that detection limits differ in virtually all past surveys, which would confound any yearly comparison if options (b) or (c), from above, are used. Historical raw data are presented in the appendices for possible supplementary study.

RESULTS

FIELD OPERATIONS

The 2001 NPDES surveys at El Segundo and Scattergood Generating Stations were conducted on 28 March, 10 August, and 20 September 2001. Latitude and longitude coordinates for water quality and benthic stations are given in Table 1.

Table 1. Latitude/longitude coordinates of sampling stations. El Segundo and Scattergood Generating Stations NPDES, 2001.

Stations		Latitude	Longitude
Water Quality	Benthic		
RW1	B1	33°56.24'	118°26.58'
RW2	B2	33°55.22'	118°26.12'
RW3	B3	33°54.27'	118°25.51'
RW4	B4	33°53.67'	118°25.33'
RW5	B5	33°56.15'	118°26.97'
RW6	B6	33°55.10'	118°26.61'
RW7	B7	33°54.09'	118°26.13'
RW8	B8	33°53.55'	118°25.78'
RW9		33°55.98'	118°27.48'
RW10		33°54.92'	118°27.05'
RW11		33°53.88'	118°26.59'
RW12		33°53.39'	118°26.22'

Water quality data were collected during ebb and flood tides in both winter and summer. Winter flood tide was sampled on 28 March between 0915 and 1100 hr, and ebb tide between 1300 and 1450 hr (Figure 5). During sampling skies changed from overcast to partly cloudy, with light winds variable from west to south at 2 to 5 kn. Seas were west to southwest 2 to 4 ft throughout the day. Tides ranged from a low of +0.3 ft Mean Lower Low Water (MLLW) at 0521 hr to a high of +3.5 ft MLLW at 1128 hr, and back to a low of +1.4 ft MLLW at 1651 hr. Summer flood tide was sampled on 20 September between 0950 and 1110 hr and ebb tide between 1245 and 1425 hr (Figure 6). Seas were southwest at 1 ft, with winds southwest calm to 3 kn. Skies were overcast to partly cloudy during sampling. The tide ranged

from a low of +0.9 ft MLLW at 0550 hr to a high of +5.6 ft MLLW at 1205 hr, and back to a low of +0.4 ft MLLW at 1842 hr.

Infauna, grain size and sediment chemistry samples were collected by biologist-divers between 0840 and 1630 hr on 10 August. Seas were southwest at 1 to 3 ft, with southwest winds 3 to 8 kn. Skies were overcast during sampling.

Pacific Standard Time		Wednesday		March 20, 2001

Pacific Daylight Time		Thursday		September 20, 2001	
Time	Height	Time	Height	Time	Height
0550	0.9'	1205	5.6'	1842	0.4'

Figure 6. Tidal rhythms during water column sampling, summer survey. El Segundo and Scattergood Generating Stations NPDES, 2001.

During the winter survey, no oil films, grease, floatables, turbidity, or red tide was observed. Drifting paper and plastic trash were observed at Stations RW1 and RW2. Western gulls (*Larus occidentalis*) were observed throughout the study area, and Heermann's gulls (*Larus heermanni*) were seen at Stations RW6 and RW11. Surf scoters (*Melanitta perspicillata*) were present at Stations RW2 and RW4; western grebes (*Aechmophorus occidentalis*) at Stations RW2, RW3, and RW5; and unidentified cormorants (*Phalacrocorax* sp.) at Stations RW2 and RW8. Caspian terns (*Sterna caspia*) were seen at Stations RW3 and RW8. California sea lions (*Zalophus californianus*) were observed at Station RW10, and common dolphins (*Delphinus delphis*) were seen at Stations RW3 and RW10. California brown pelicans (*Pelecanus occidentalis californicus*) were seen at Stations RW2 and RW8. No California least terns (*Sterna antillarum browni*) were observed during any component of the winter survey.

During the summer surveys, no oil films, grease, turbidity, or red tide was observed. Drift kelp (*Macrocystis pyrifera*) or seagrass (*Phyllospadix torreyi*) was seen at most stations during benthic sampling. Western and Heermann's gulls were observed throughout the study area during water quality sampling; during benthic sampling western gulls were seen at Stations RW2 and RW5, and Heermann's gulls were seen at Stations B6, B7, and B8. Western grebes were seen at Station RW2, unidentified terns at Station B7 and B8, and unidentified cormorants at Stations B7 and RW16. California sea lions were seen at Station RW9 and on buoys near Station RW10. California brown pelicans were seen at Stations B3, B5, RW1, RW2, RW3, RW6, and RW10. No California least terns were observed during any component of the summer survey.

WATER COLUMN MONITORING

Receiving water monitoring stations are shown in Figure 3. Water quality data for ebb and flood tides are summarized in Table 2 and are provided for each survey in Figures 7 through 10. Raw data are presented in Appendix C.

Temperature

In winter, mean surface water temperature during ebb tide was 16.42°C; temperatures ranged from 15.82°C at Station RW10 to 17.29°C at Station RW7 (Table 2 and Figure 7).

Temperatures during flood tide were generally cooler at the surface, with a mean surface water temperature of 15.77°C and a range from 15.45°C at Station RW6 to 16.68°C at Station RW3. The mean bottom temperature was 12.77°C during ebb tide and 13.82°C on flood tide. Bottom temperatures ranged from 11.58°C at Station RW11 to 15.35°C at Station RW2 during ebb tide and from 11.76°C at Station RW12 to 15.66°C at Station RW2 during flood tide. Temperature on flood tide decreased gradually with depth at all stations, while on ebb tide, temperatures also decreased to the bottom, but strong thermoclines were noted at 2 to 8 m. Slightly greater surface-to-bottom differences were found during ebb tide. The maximum surface-to-bottom differences recorded were 5.49°C at Station RW7 during ebb tide and 3.81°C at Station RW12 on flood tide.

Table 2. Summary of water quality parameters during ebb and flood tides. El Segundo and Scattergood Generating Stations NPDES, 2001.

	Temp. (°C)		D.O. (mg/l)		pH		Salinity (ppt)		Temp. (°C)		D.O. (mg/l)		pH		Salinity (ppt)	
	Winter

Minimum	15.82	15.45	7.77	7.92	8.06	8.05	33.13	33.14	11.58	11.76	4.83	5.02	7.76	7.76	33.28	33.21
Maximum	17.29	16.68	9.15	8.60	8.18	8.13	33.24	33.27	15.35	15.66	8.72	8.56	8.08	8.10	33.62	33.55
	Summer															
	Surface								Bottom							
	ebb	flood	ebb	flood	ebb	flood	ebb	flood	ebb	flood	ebb	flood	ebb	flood	ebb	flood
Mean	20.17	20.15	7.97	7.79	8.00	8.00	33.53	33.50	15.82	15.96	7.88	7.89	7.90	7.91	33.49	33.51
Minimum	19.63	19.67	7.60	7.57	7.96	7.97	33.38	33.20	14.92	14.42	7.28	7.41	7.87	7.86	33.43	33.46
Maximum	20.48	20.42	8.19	7.98	8.02	8.02	33.57	33.58	16.94	18.27	8.43	8.34	7.94	7.95	33.63	33.56

In summer, mean surface water temperature during ebb tide was 20.17°C; temperatures ranged from 19.63°C at Station RW9 to 20.48°C at Station RW4 (Table 2). Temperature decreased with depth on both tides; however, on ebb tide the thermoclines were typically at a deeper depth (Figure 7). Surface temperatures were similar between tides, but water at mid-depth was typically warmer on ebb tide than on flood tide. Mean surface water temperature during flood tide was 20.15°C, with temperatures ranging from 19.67°C at Station RW12 to 20.42°C at Station RW3. Strong thermoclines were present at 3 to 4 m at Stations RW3 and RW4. Bottom temperatures were similar between flood and ebb tides at most stations. Near-bottom temperatures at Stations RW1 and RW3 were notably cooler on ebb tide. The mean bottom temperature during ebb tide was 15.82°C and during flood tide was 15.96°C. Bottom temperatures ranged from 14.92°C at Station RW10 to 16.94°C at Station RW2 during ebb tide, and from 14.42°C at Station RW10 to 18.27°C at Station RW3 on flood tide. The maximum surface-to-bottom difference was recorded at Station RW11 during ebb tide (5.24°C). During flood tide the maximum surface-to-bottom difference was 5.58°C at Station RW10.

Dissolved Oxygen

In winter, surface dissolved oxygen (DO) concentrations averaged 8.48 mg/l during ebb tide, ranging from 7.77 mg/l at Station RW4 to 9.15 mg/l at Station RW5 (Table 2). During flood tide, the mean surface DO concentration was 8.33 mg/l, ranging from 7.92 mg/l at Station RW3 to 8.60 mg/l at Station RW5. Surface DO levels were similar between tides at most stations with the exception of Stations RW4, RW5, RW6, and RW9, where ebb tide surface DO was about 0.5 to 1.5 mg/l higher than that during flood tide. During ebb tide, DO concentrations typically increased to 4 to 8 m then decreased rapidly to the bottom (Figure 8). During flood tide, DO concentrations among inshore stations were similar and increased slightly to the bottom; at the mid-depth and offshore stations, DO typically increased slightly to about 4 to 8 m and then decreased with depth. Flood tide bottom DO concentrations were typically 1 to 2 mg/l more than those during ebb tide. Mean surface DO was slightly higher during ebb tide, while mean bottom DO was higher during flood tide. The

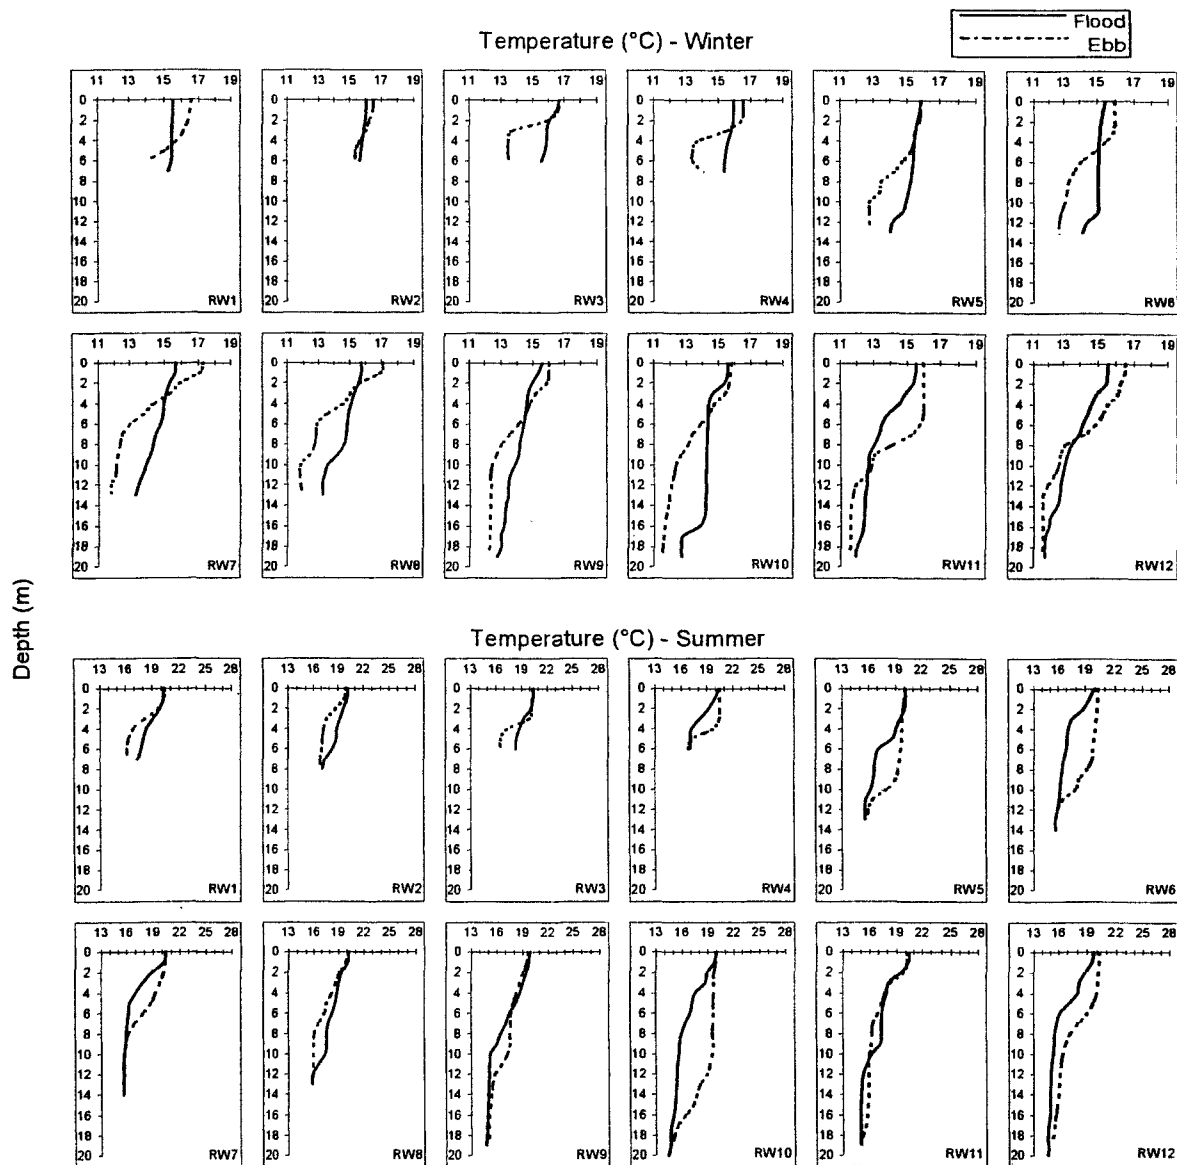

Figure 7. Temperature vertical profiles during flood and ebb tides. El Segundo and Scattergood Generating Stations NPDES, 2001.

mean bottom DO during ebb tide was 6.14 mg/l and during flood tide was 7.13 mg/l. The lowest bottom values occurred at Station RW12 on both tides, with a DO of 4.83 mg/l on ebb tide, and 5.02 mg/l on flood tide. The highest bottom value on flood and ebb tides were found at Station RW1 with concentrations of 8.56 mg/l on ebb tide and 8.72 mg/l on flood tide. The maximum surface-to-bottom difference in DO concentration occurred at Station RW10 on ebb tide, with a decrease of 3.69 mg/l and during flood tide the maximum difference was 3.39 mg/l at Station RW12. The greatest overall change in DO occurred between 9 m depth and the bottom at Station RW11 on ebb tide, with a difference of 4.25 mg/l.

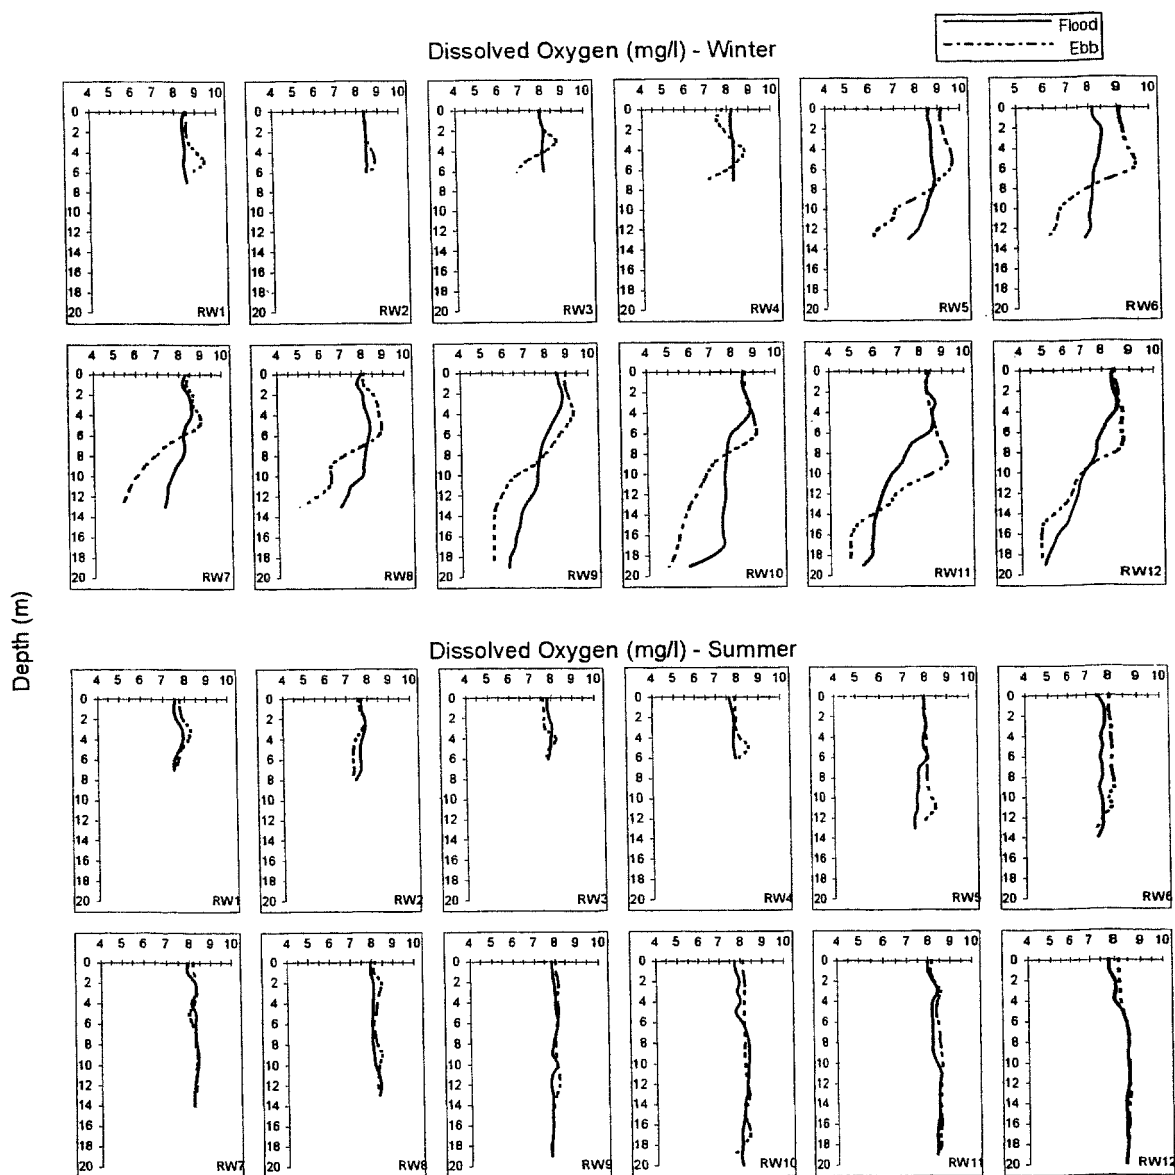

Figure 8. Dissolved oxygen vertical profiles during flood and ebb tides. El Segundo and Scattergood Generating Stations NPDES, 2001.

In summer, mean surface DO concentrations were 7.97 mg/l during ebb tide and 7.79 mg/l during flood tide (Table 2). During ebb tide, surface DO values ranged from 7.60 mg/l at Station RW2 to 8.19 mg/l at Station RW7. During flood tide, surface DO ranged from 7.57 mg/l at Station RW1 to 7.98 mg/l at Station RW11. Flood tide surface DO values were similar to, but in general slightly lower than, ebb tide measurements (Figure 8). The greatest difference occurred at Station RW6, with a 0.44 mg/l difference between tides. During both tides, DO values were mixed with five stations with surface DO higher than bottom, and six stations with bottom DO higher. At Station RW10, flood tide values were higher at the bottom, and ebb tide at the surface. Mean bottom DO concentrations were 7.88 mg/l during ebb tide and 7.89 mg/l during flood tide (Table 2). During ebb tide, bottom DO values ranged from 7.28 mg/l at Station RW2 to 8.43 mg/l at Station RW12. During flood tide, bottom DO ranged from 7.41 mg/l at Station RW2 to 8.34 mg/l at Station RW11. Maximum DO values were typically found at mid-depth. Below the mid-depth maximum, DO

generally decreased with increasing depth. Profiles were similar among stations, with the greatest surface-to-bottom difference of 0.56 mg/l at Station RW6 on ebb tide and 0.53 mg/l at Station RW12 on flood tide. The largest decline below the maximum was 0.73 mg/l on ebb tide at Station RW10 between the mid-water DO concentration peak at 13 m and the bottom.

Hydrogen Ion Concentration

In winter, hydrogen ion concentration (pH) at the surface averaged 8.11 during ebb tide, differing less than 0.07 from the values at all stations (Table 2). During flood tide, mean surface pH was 8.09, with values varying 0.04 or less at all stations. Values generally decreased with depth and were typically lower on ebb tide in the water column below 2 to 6 m (Figure 9). The maximum surface-to-bottom difference was 0.55 at Station RW10 on ebb tide.

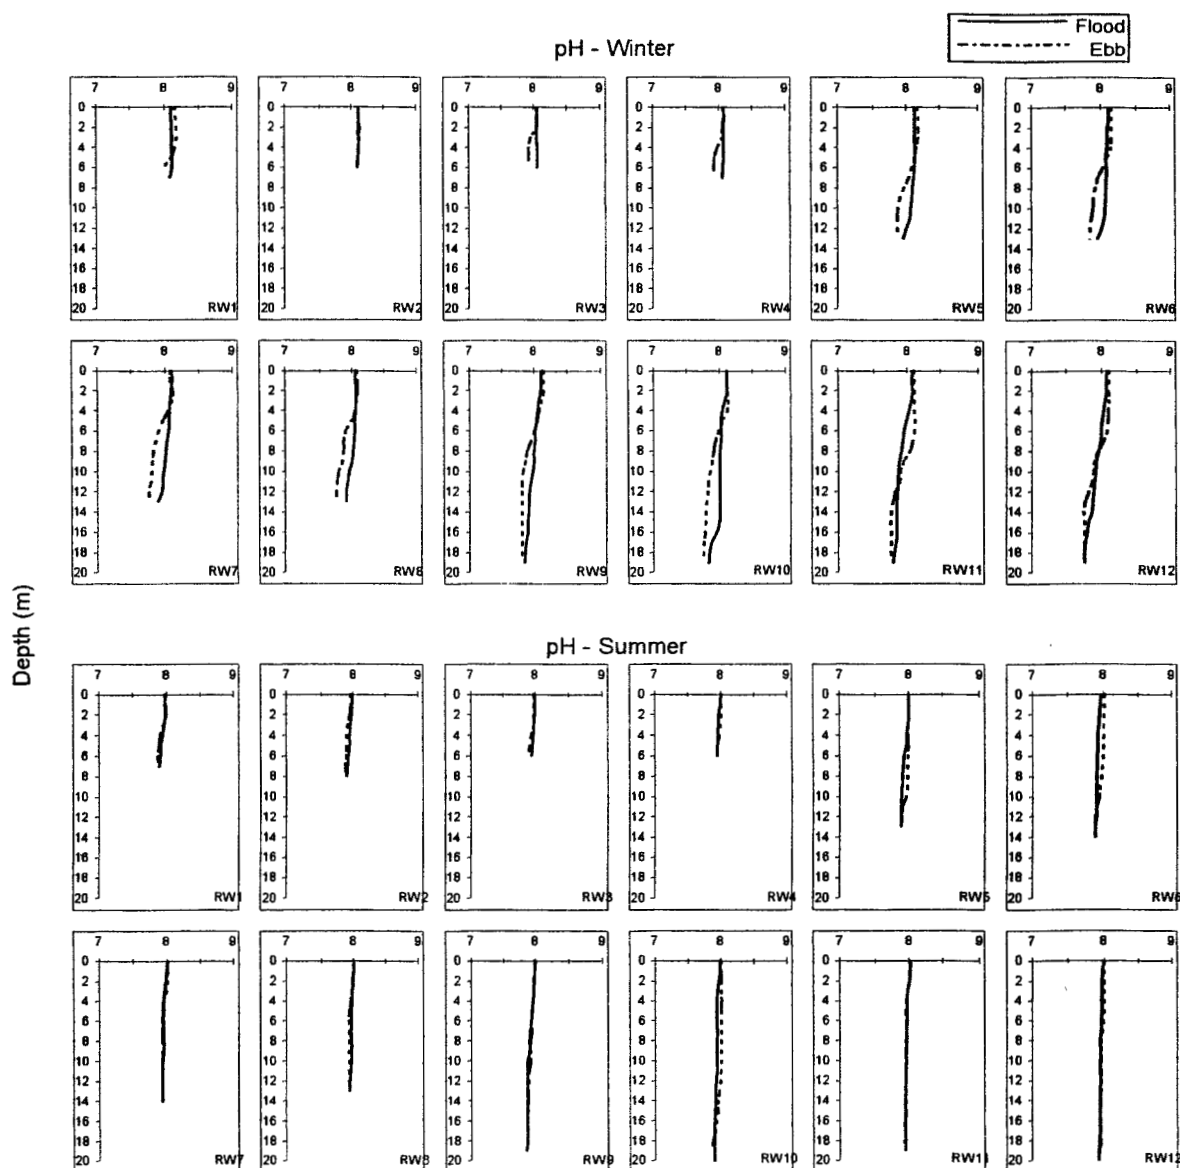

Figure 9. Hydrogen ion concentration (pH) vertical profiles during flood and ebb tides. El Segundo and Scattergood Generating Stations NPDES, 2001.

In summer, mean surface pH was 8.00 during both tides, with values differing from the mean 0.04 or less on either tide (Table 2). At all stations, pH levels were nearly identical throughout the water column averaging 7.90 on ebb tide and 7.91 on flood tide (Figure 9). A maximum difference of 0.14 was found between tides and among stations.

Salinity Concentration

In winter, salinity concentration at the surface averaged 33.21 parts per thousand (ppt) during ebb tide and was nearly identical (33.22 ppt) during flood tide, differing less than 0.08 ppt from the average at all stations on both tides (Figure 10, Table 2). Values generally increased with depth at mid-depth and deeper stations, but was more variable at the inshore stations. With the exception of Station RW9, ebb tide values were typically higher at depth and generally exhibited

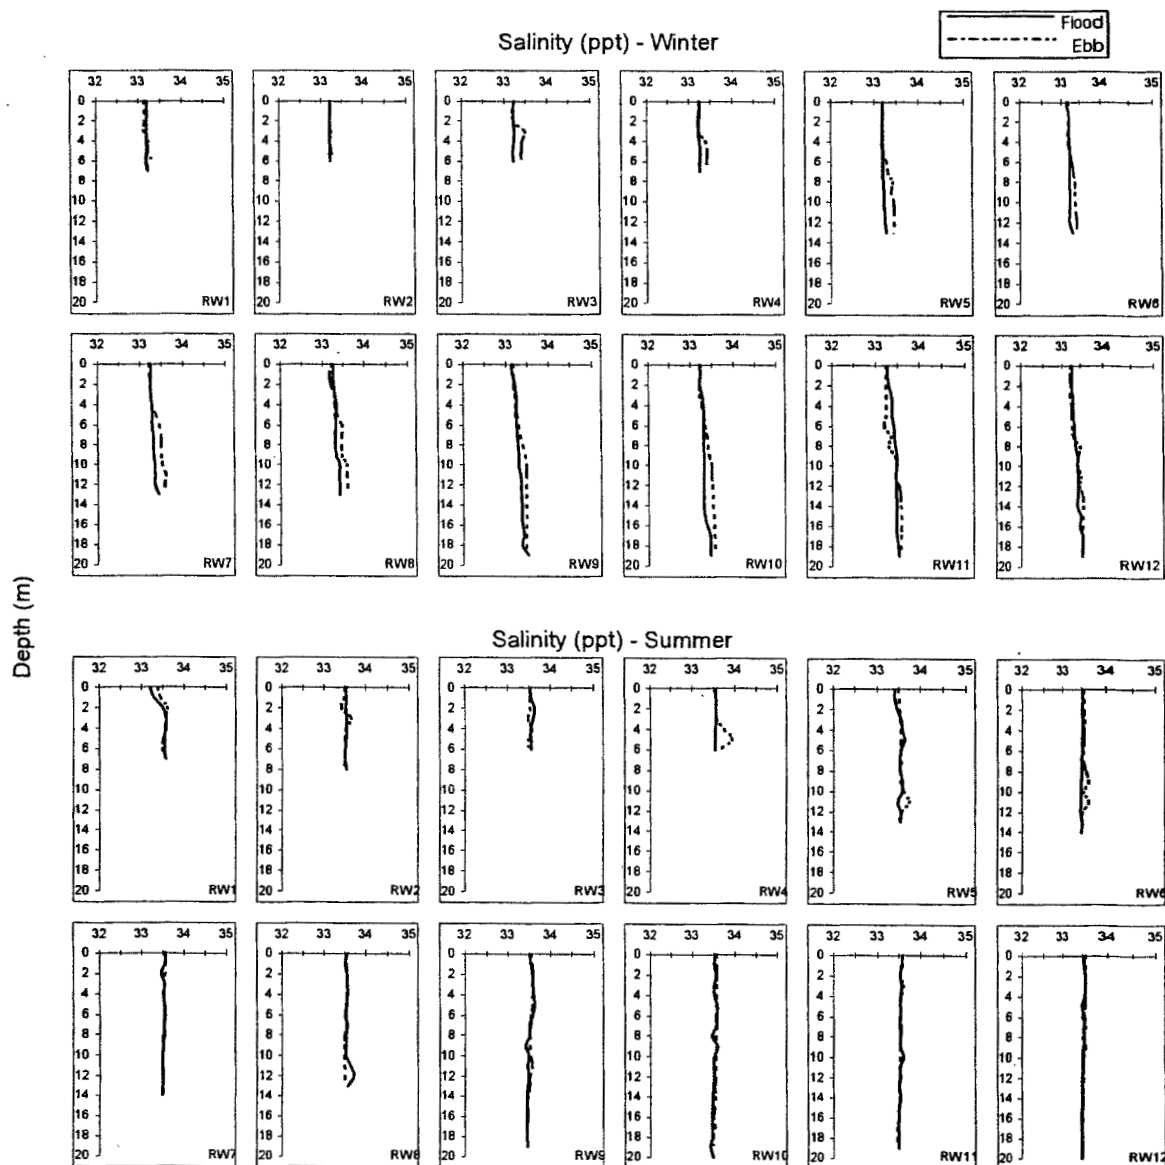

Figure 10. Salinity vertical profiles during flood and ebb tides. El Segundo and Scattergood Generating Stations NPDES, 2001.

small haloclines at 3 to 6 m depth (Figure 10). The maximum surface-to-bottom difference was 0.40 ppt at Station RW8 on ebb tide and 0.39 ppt at Station RW9 on flood tide. Salinity at the bottom averaged 33.47 ppt on ebb tide and 33.37 ppt on flood tide and varied by 0.22 ppt between tides and 0.41 ppt among stations.

In summer, mean surface salinity was 33.53 ppt on ebb tide and nearly identical (33.50 ppt) during flood tide, with values differing from the mean by 0.3 ppt or less on either tide (Table 2). Salinity levels were generally identical through the water column on both tides; however, at the inshore stations a halocline was noted at 0 to 4 m depth on ebb tide and slightly deeper at the mid-depth stations, while tiny excursions were noted at the deep stations (Figure 10). Mean bottom salinity was again nearly identical between tides with 33.49 ppt on ebb tide and 33.51 ppt on flood tide. A maximum difference of 0.18 ppt was found between tides and 0.54 ppt among stations.

SEDIMENT MONITORING

Sediment Grain Size

Particle size distribution curves for each station are presented in Appendix D and sediment grain size parameters are summarized in Table 3. Grain size is expressed in phi (Φ) units, which are inversely related to grain diameter.

In 2001, sediments at all stations were composed primarily of sand with smaller amounts of silt and clay (Table 3). Overall, samples from the eight stations averaged 89% sand, 10% silt, and 1% clay, with an average mean grain size of 2.46 phi (182 μ m, fine sand). Sediments were finest at inshore Station B2 (upcoast of the Scattergood discharge structure at a depth of 20 ft), where mean grain size was 3.62 phi (81 μ m). Coarsest sediments were collected from offshore Station B5 (upcoast of the Scattergood discharge at a depth of 40 ft), where mean grain size was 0.73 phi (604 μ m). Sediments at the nearshore stations averaged 83% sand, with a mean grain size of 3.01 phi (124 μ m) while sediments at the offshore stations averaged 96% sand, with a mean grain size of 2.06 phi (239 μ m).

Table 3. Sediment grain size parameters. El Segundo and Scattergood Generating Stations NPDES, 2001.

Parameter	Nearshore					Offshore					Overall	
	B1	B2	B3	B4	Mean	B5	B6	B7	B8	Mean	Mean	S.D.

% Silt	23.07	36.07	1.34	3.19	15.92	1.21	5.83	3.28	3.16	3.37	9.64	12.86
% Clay	1.90	2.51	0.45	0.85	1.43	0.17	1.50	1.15	1.41	1.06	1.24	0.76
Mean grain size												
phi	3.58	3.62	2.39	2.82	3.01	0.73	3.15	3.06	3.04	2.06	2.46	0.92
μ m	83	81	191	142	124.3	604	112	120	121	239.3	181.8	174.1
Sorting (ϕ)	0.68	1.20	0.64	0.59	0.78	0.91	0.53	0.46	0.49	0.60	0.69	0.25
Skewness	0.14	0.06	-0.02	0.03	0.05	-0.08	0.17	0.07	0.03	0.05	0.05	0.08
Kurtosis	1.12	1.01	1.02	1.10	1.06	1.12	1.27	1.14	1.18	1.18	1.12	0.08

Sorting, a measure of the spread of the particle distribution curve, averaged 0.69 phi overall, indicating moderately well sorted sediments (Table 3). Sorting values ranged from 0.46 phi (well sorted) at offshore Station B7 to 1.20 phi (poorly sorted) at nearshore Station B2. Poorly sorted sediments are composed of a broad range of particle size classes, while well sorted sediments contain only a few size classes.

Skewness and kurtosis tell how closely the grain size distribution approaches the normal Gaussian probability curve. More extreme skewness and kurtosis values indicate non-normal

Skewness and kurtosis indicates how closely the grain size distribution approaches the normal Gaussian probability curve. More extreme skewness and kurtosis values indicate non-normal distributions. Skewness is a measure of the symmetry of the particle distribution curve; a value of zero indicates a symmetrical distribution of fine and coarse materials around the mode of the curve, while a value greater than zero (positive) indicates an excess of fine material, and a negative value indicates an excess of coarse material. Sediments at all stations were slightly skewed; average skewness was 0.05 (Table 3). Sediments at Station B3 were the most evenly distributed with a skewness of -0.02, indicating a slightly greater amount of coarse material in the sediments (Appendix D). The greatest skewness was 0.17, found at Station B6.

Kurtosis is a measure of the peakedness of the particle distribution curve. A kurtosis value of 1.00 represents a normal particle distribution curve. Kurtosis values at all stations were greater than 1.00, indicating leptokurtic (excessively peaked) distributions, with dominance by a narrow range of particle sizes (Table 3). Kurtosis values were lowest at the nearshore stations, while highest kurtosis occurred at Station B6.

Sediment Chemistry

Concentrations of metals found in sediments at each station are presented in Appendix E and are summarized in Table 4. In 2001, concentrations of all metals were highest at inshore Stations B1 and B2 (Table 4). Lowest concentrations of chromium, copper, and zinc were detected at nearshore Station B3, and lowest nickel concentration occurred at offshore Station B5. Overall, chromium concentrations ranged from 9.4 to 24 mg/kg, copper from less than 1.6 to 8.8 mg/kg, nickel from 3.1 to 13 mg/kg, and zinc ranged from 12 to 48 mg/kg.

Table 4. Sediment metal concentrations (mg/dry kg). El Segundo and Scattergood Generating Stations NPDES, 2001.

MUSSEL BIOACCUMULATION

In 2001, forty-five (45) bay mussels (*Mytilus edulis*) each were collected from the Scattergood discharge structure and from each of the El Segundo Units 1 & 2 and Units 3 & 4 discharge structures.

Copper was detected in four of the six replicate samples of bay mussel tissue collected from the El Segundo Units 1&2 and 3&4 discharge and all three replicates from the Scattergood discharge structure (Table 5, Appendix F). Zinc was detected in all replicates from both El Segundo and Scattergood discharge structures locations. Mean concentration of copper, where detected, was 6.4 mg/dry kg at El Segundo and 9.8 mg/dry kg at Scattergood. Mean concentration of zinc was 68 mg/dry kg at El Segundo and 51.3 mg/dry kg at Scattergood. Chromium and nickel were not detected in any of the replicates.

BIOLOGICAL MONITORING

Benthic Infauna

Results of infaunal analyses for 2001 are presented by station and replicate in Appendix G and are summarized in Tables 6, 7, and 8 and Figure 11.

Species Composition. A total of 3,884 infaunal organisms representing 196 species and 12 phyla were collected during the summer survey (Table 6, Appendix G-1). Annelida was the most abundant phylum, but was second in species richness, accounting for almost 55% of the individuals but only slightly more than 31% of the species. The phylum Arthropoda was second most abundant, accounting for nearly 28% of the individuals, but was first in species richness with almost 38% of the species. Mollusca was the third most abundant phylum, comprising more than 17% of individuals and almost 11% of the species. Nemertea represented 3.6% of the species but only about 2.0% of the individuals, while Echinodermata represented 2.6% of the species and 0.2% of the abundance. The eight remaining phyla together represented less than 2% of the individuals and 8% of the species. Three phyla, Brachiopoda, Sipuncula, and Nematoda, were represented by only one species each; only one individual of Brachiopoda and Sipuncula occurred in the samples. Arthropods, mollusks, and echinoderms were generally more abundant and speciose offshore than nearshore; the exception was the high abundance of mollusks at Station B2.

Number of Species. Species richness averaged 58 species per station and ranged from 21 species at Station B3 to 80 species at Station B5 (Table 7). Species richness was higher at offshore stations (an average of 73 species per station) than at nearshore stations (an average of 43 species). Nearshore, species richness was highest at Stations B1 and B2, both upcoast of the

Scattergood Generating Station, and lowest at Station B3, immediately downcoast of the El Segundo Generating Station. Offshore, species richness was greatest furthest upcoast and lowest downcoast.

Abundance and Density. Abundance averaged 486 individuals per station and ranged from 127 individuals at Station B3 to 761 individuals at Station B4, nearshore and immediately downcoast of El Segundo Generating Station (Table 7). Density averaged 12,138 individuals/m², and ranged from 3,175 individuals/m² to 19,025 individuals/m². On average, abundance and density were greater nearshore (534 individuals per station and 13,356 individuals/m², respectively) than offshore (437 individuals per station and 10,919 individuals/m², respectively). The high abundance values at Stations B1, B2, and B4 were due to large numbers (453, 313, and 599, respectively) of the polychaete annelid *Apoprionospio pygmaea* (Table 8). Abundance of this species at Station B3 and at the offshore stations ranged from 4 at Station B5 to 40 at Station B3.

Species Diversity. Shannon-Wiener species diversity index (H') values totaled 3.19 and averaged 2.48 per station, and ranged from 1.12 at Station B4 to 3.54 at Station B5 (Table 7). The value at Station B4 was particularly low because of the overwhelming numerical dominance of the community by *Apoprionospio pygmaea*. All of the offshore station values were greater than any of the nearshore station values.

Biomass. Biomass averaged 1.92 g per station, or 48 g/m². Biomass was highest at Station B2 (6.49 g, or 162.25 g/m²) due to the occurrence of the annelid *Apoprionospio pygmaea* and a mollusk (Table 7, Appendices G-3 and G-4). Biomass was lowest at Station B3 (0.64 g). Biomass at the nearshore stations was generally less than that at the offshore stations, however the greatest biomass was taken at a nearshore station.

Community Composition. The 18 most abundant species, those which each comprised 1% or more of the total abundance, accounted for almost 76% of all the organisms collected (Table 8). The most abundant species, the annelid worm *Apoprionospio pygmaea*, accounted for almost 39% of all individuals taken. Next most abundant was the annelid worm *Diastylopsis tenuis*, comprising more than 6% of the individuals and taken at 6 of the 8 stations. Third most abundant with almost 6% of the abundance was the mollusk *Tellina modesta*, which occurred throughout most of the study area. The Pacific sand dollar (*Dendroaster excentricus*) occurred in greater numbers offshore, while the three amphipods *Rhepoxynius abronius*, *Mandibulophoxus gilesi*, and

Rhepoxynius menziesi were relatively abundant comprising 2.6, 2.3, and 2.1% of the individuals, respectively. Both of the *Rhepoxynius* congeners were found in greater abundance offshore, whereas the amphipod *Mandibulophoxus gilesi* was found exclusively at onshore Stations B3 and B4 (Table 8).

Cluster Analysis. Results of cluster analysis (classification) of the 18 most abundant infaunal species (Table 8) are presented in Figure 11.

Normal (site) analysis clustered the eight stations into three groups (Figure 13). Group I contains offshore Stations B6, B7, B8, where several of the more abundant species occurred in relatively equal concentrations. Group II included all of the nearshore stations (Stations B1, B2, B3, and B4); the top species were very abundant at most of these stations and other species occurred in similar abundance. Group III included only the offshore, upcoast Station B5, where several other species were more abundant, and a few were less abundant than the other offshore stations.

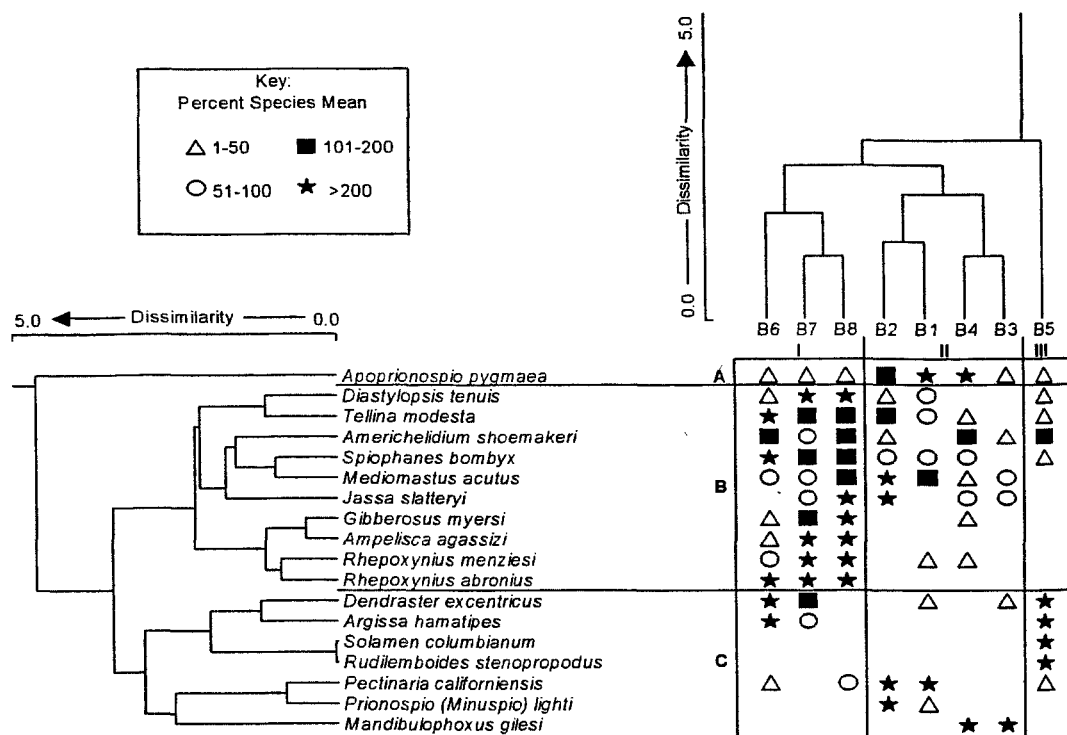

Figure 11. Two-way coincidence table resulting from normal (station) and inverse (species) classification dendrograms for the 18 most abundant infaunal species. El Segundo and Scattergood Generating Stations NPDES, 2001.

Inverse (species) analysis clustered the dominant species into three species groups. Group A included only the amphipod *Apoprionospio pygmaea*, which was widely distributed. Group B included very abundant species at the offshore stations and moderately abundant species which occurred at several stations in the inshore area. Group C comprised the remaining seven species, which typically were very abundant at only one station and did not occur at several stations.

Impingement

Results from heat treatment and normal operation surveys of fish entrained and impinged at El Segundo Generating Station and from heat treatment surveys at Scattergood Generating Station during the 2001 sampling year (1 October 2000 To 30 September 2001) are presented in the

following text. Data are summarized in Tables 9 through 12 and presented in their entirety in Appendix H. Fish and macroinvertebrate data are presented separately for each generating station.

Fish

Species Composition. In total, 57 species representing two classes and 30 families of fish were taken at the two generating stations (Appendix H-1).

El Segundo. Heat treatment and normal operation surveys at Units 1 & 2 yielded 35 species of fish representing two classes and 21 families (Appendices H-1 and H-2). Four families of cartilaginous fish (Elasmobranchiomorpha = Chondrichthyes) and 17 families of bony fish (Osteichthyes) were dominated by five species each of surfperch in the family Embiotocidae and croakers in the family Sciaenidae. Heat treatment and normal operation surveys at El Segundo Generating Station Units 3 & 4 yielded 36 species of fish representing two classes and 22 families (Appendices H-1 and H-2). Four families of cartilaginous fish and 18 families of bony fish were dominated by six species of surfperch and four species of croakers. A total of 45 species were taken at El Segundo Generating Station (Table 9); nine species were unique to Units 1 & 2, and 10 species were unique to Units 3 & 4.

Table 9. Number of individuals and biomass (kg) of the 10 most abundant fish species impinged during heat treatments at El Segundo Generating Station. El Segundo and Scattergood Generating Stations NPDES, 2001.

Total Species	35		36		45			

Scattergood. Heat treatment surveys at Scattergood Generating Station yielded 47 species of fish, representing two classes and 26 families (Table 10, Appendices H-1 and H-3). Five families of cartilaginous fish and 21 families of bony fish were dominated by six species each of croakers and surfperch.

Table 10. Number of individuals and biomass (kg) of the five most abundant fish species impinged during heat treatments at Scattergood Generating Station. El Segundo and Scattergood Generating Stations NPDES, 2001.

Common Name	Abundance	Biomass	Percent		Cumulative Percent	
			Abundance	Biomass	Abundance	Biomass
Pacific sardine	19932	671.37	50.8	31.6	50.8	31.6
queenfish	10620	312.62	27.1	14.7	77.8	46.4

white croaker	589	30.95	1.5	1.5	96.0	65.9
Survey Totals	39256	2122.87				
Total Species	47					

Abundance. An estimated total of 43,990 individual fish were taken at the two generating stations; 39,256 fish (89.2%) were taken from Scattergood Generating Station and 4,734 (10.8%) from El Segundo Generating Station (Tables 9 and 10, Appendices H-2 and H-3).

El Segundo. There were 1,732 individuals taken during three heat treatments at Units 1 & 2, and 2,673 individuals taken at four heat treatments at Units 3 & 4 (Table 11, Appendix H-4). Catch per heat treatment at the Units 1 & 2 screenwell averaged 577 individuals and 20 species, and ranged from 164 individuals and 17 species (1 February 2001) to 1,291 individuals (30 April 01) and 22 species (22 December 2000 and 30 April 2001). Extrapolated abundance based on the intake flow during the six normal operation surveys indicated approximately 205 fish were impinged during the year, giving an estimated total of 1,937 individuals and 35 species taken at El Segundo

Generating Station Units 1 & 2 (Appendix H-5). Catch per heat treatment at the Units 3 & 4 screenwell averaged 668 individuals and 20 species, and ranged from 82 individuals and 10 species (26 August 2001) to 1,265 individuals (8 July 2001) and 24 species (7 October 2000 and 8 July 2001). Extrapolated abundance based on the intake flow during the 10 normal operation surveys indicated that approximately 124 fish were impinged during the year, giving an estimated total of 2,797 individuals and 36 species taken at El Segundo Generating Station Units 3 & 4 (Appendix H-6). The combined abundance at El Segundo Generating Station was an estimated 4,734 individuals of 45 species (Table 9, Appendix H-2).

Queenfish (*Serphus politus*) was the most abundant species overall, accounting for 42.9% (2,007) of the individuals; it was the most abundant species at Units 3 & 4, and second in abundance at Units 1 & 2 (Table 9).

Northern anchovy (*Engraulis mordax*), second in overall abundance, was first in abundance at Units 1 & 2, while it ranked 17th at Units 3 & 4. The second, third, and fourth most abundant species overall were salema (*Xenistius californiensis*), walleye surfperch (*Hyperprosopon argenteum*), and sargo (*Anisotremus davidsonii*) which contributed 7.3%, 6.5%, and 5.9% to the overall abundance, respectively. Kelp bass (*Paralabrax clathratus*), jacksmelt (*Atherinopsis californiensis*), blacksmith (*Chromis punctipinnis*), shiner perch (*Cymatogaster aggregata*), and white seaperch (*Phanerodon furcatus*) were the sixth through tenth, respectively, most abundant fish overall. These five species accounted for 11.3% of the combined abundance. The 10 most abundant species at El Segundo Generating Station accounted for 91.1% of all individuals taken. The remaining 35 species accounted for 531 individuals and less than 9% of the abundance. Of the top ten most abundant species overall, most of the species had similar ranks at Units 3 & 4; two of these species, salema and shiner perch, were not taken at Units 1 & 2. Other species among the ten most abundant at Units 1 & 2 were California scorpionfish (*Scorpaena guttata*), California halibut (*Paralichthys californicus*), and horn shark (*Heterodontus francisci*). Other species among the ten most abundant at Units 3 and 4 were barred sand bass (*Paralabrax nebulifer*) and black croaker (*Cheilotrema saturnum*).

Scattergood. Five heat treatments were conducted at Scattergood Generating Station, with the catch per heat treatment averaging 7,851 individuals and 26 species (Table 12). The catch

ranged from 2,059 individuals and 17 species (27 March 2001) to 24,910 individuals and 32 species (14 November 2000) (Table 12, Appendix H-3).

Pacific sardine (*Sardinops sagax*) was the most abundant species, accounting for 50.8% (19,932 individuals) of the abundance, followed by queenfish, with 27.1% (10,620 individuals) of the abundance (Table 10). The third, fourth, and fifth most abundant species were topsmelt (*Atherinops affinis*), jacksmelt, and white croaker (*Genyonemus lineatus*) which contributed 9.7%, 7.1%, and 1.5% to the abundance, respectively. The five most abundant species at Scattergood Generating Station accounted for 96.0% of all the individuals taken at the station (Table 10). The remaining 27 species totaled 1,556 individuals and accounted for only 4.0% of the abundance.

Biomass. Biomass totaled 2,759.99 kg for fish impinged at both stations (Tables 9 and 10). Scattergood Generating Station accounted for 76.9% (2,122.87 kg) of the overall total and El Segundo Generating Station accounted for 23.1% (637.12 kg).

El Segundo. Fish biomass totaled 238.0 kg during the heat treatment surveys at El Segundo Generating Station Units 1 & 2, and 257.04 kg at the heat treatment surveys at Units 3 & 4 (Table 11, Appendix H-7). Biomass at Units 1 & 2 heat treatments averaged 79.3 kg, and ranged from 51.8 kg (22 December 2000) to 112.5 kg (30 April 2001), and at Units 3 & 4 averaged 64.3 kg, ranging from 8.1 kg (26 August 2001) to 115.4 kg (7 October 2000) (Table 11). Combined with normal operation surveys, estimated fish biomass totaled 637.1 kg at El Segundo Generating Station in 2001 (Appendix H-2). The eight species ranked highest in biomass at El Segundo Generating Station were, in order, horn shark, sargo, kelp bass, queenfish, bat ray (*Myliobatis californica*), salema, opaleye (*Girella nigricans*), and walleye surfperch. Individually, these species contributed greater than 2% to the biomass, and collectively, these eight species amassed a weight of 502.95 kg or 78.9% of the biomass at El Segundo Generating Station (Appendix H-2). Other species ranked high in biomass at Units 1 & 2 were northern anchovy, swell shark (*Cephaloscyllium ventriosum*), and California sheephead (*Semicossyphus pulcher*). At Units 3 & 4, other highly ranked species were barred sand bass and jacksmelt.

Scattergood. In 2001 fish biomass totaled 2,122.87 kg during the five heat treatment surveys at Scattergood Generating Station (Table 12, Appendix H-8). Biomass averaged 424.6 kg per survey and ranged from 97.4 kg (27 March 2001) to 1,117.6 kg (14 November 2000). Pacific sardine accounted for 31.6% of the biomass; this species and the next five highest ranking species (bat ray, queenfish, jacksmelt, topsmelt, and barred sand bass) accounted for 88.9% (1,887.6 kg) of the total biomass (Appendix H-8). Four of these six species were among the six most abundant species.

Size (Length). Standard length (SL), total length (TL), or disk width (DW), where appropriate, were measured in mm for up to 200 individuals of each species impinged during heat treatment and normal operation surveys.

Table 12. Number of species, number of individuals, and biomass (kg) of fish impinged during heat treatments at Scattergood Generating Station. El Segundo and Scattergood Generating Stations NPDES, 2001.

Population Structure. Length-frequency histograms were constructed for one of the more abundant forage species, queenfish, and two species of sport fishing importance, kelp bass and barred sand bass. These species were sufficiently abundant at one or both of the stations to construct meaningful histograms, which were utilized to determine if the intake selectively entrained

particular size classes. These histograms do not necessarily reflect the composition of the offshore population.

Queenfish was one of the most numerous fish taken in 2001. It was most frequently entrained at the 110 to 150 mm SL size range at the two generating stations. At El Segundo Generating Station there were three mode, at 70, 100 and 130 mm SL (Figure 12). At Scattergood Generating Station, there was a single mode at 130 mm SL.

Figure 12. Length-frequency distribution of queenfish (*Seriphus politus*) taken during impingement surveys. El Segundo and Scattergood Generating Stations NPDES, 2001.

Kelp bass size distribution indicated a single mode in the population at El Segundo Generating Station, with two modes at Scattergood Generating Station. Distribution at El Segundo Generating Station peaked at 230 mm SL; distribution at Scattergood Generating Station peaked at 80 and 160 mm SL (Figure 13). At El Segundo Generating Station most of the individuals were between 200 and 310 mm SL, and at Scattergood Generating Station most were less than 100 mm SL. Kelp bass were more abundant at El Segundo Generating Station.

Figure 13. Length-frequency distribution of kelp bass (*Paralabrax clathratus*) taken during impingement surveys. El Segundo and Scattergood Generating Stations NPDES, 2001.

Barred sand bass size distribution indicated a single mode in the populations at both El Segundo Generating Station and Scattergood Generating Station. Distribution at El Segundo Generating Station peaked at 210 mm SL; at Scattergood Generating Station the population peaked

at 230 mm SL (Figure 14). At El Segundo Generating Station most of the individuals were between 190 and 310 mm SL, and at Scattergood Generating Station most were between 200 and 240 mm SL. Barred sand bass were more abundant at Scattergood Generating Station.

Figure 14. Length-frequency distribution of sand bass (*Paralabrax nebulifer*) taken during impingement surveys. El Segundo and Scattergood Generating Stations NPDES, 2001.

Diseases and Abnormalities. No diseases were noted on any fish caught during the impingement surveys. However, during the July heat treatment at Scattergood Generating Station, two bat rays were missing all or part of their tails, and a species of parasitic fish lice, *Elthusa* (= *Lironeca*) sp., was present on a salem.

Macroinvertebrates

El Segundo. Fourteen motile macroinvertebrate species, with an estimated abundance of 32,419 individuals and a biomass of 1,569.2 kg were collected during heat treatment and normal operation surveys at El Segundo Generating Station (Table 13, Appendices H-9 through H-13). These species represented four phyla and 10 families, and included nine species of arthropods (all crustaceans), two species each of echinoderms and mollusks, and one cnidarian (Appendix H-1).

Table 13. Number of individuals and biomass (kg) of the five most abundant macroinvertebrates impinged during heat treatments at El Segundo Generating Station. El Segundo and Scattergood Generating Stations NPDES, 2001.

Species	Units 1 & 2		Units 3 & 4		Total Abundance	Percent Total	Cumulative Percent	Total Biomass
	Abund.	Biomass	Abund.	Biomass				
Pacific rock crab	15049	145.23	12617	629.85	27666	85.34	85.34	775.08
yellow rock crab	512	16.11	1129	45.92	1641	5.06	90.40	62.03
graceful rock crab	22	0.05	876	36.45	898	2.77	93.17	36.50
purple jellyfish	3	2.70	736	461.77	739	2.28	95.45	464.47
tuberculate pear crab	37	0.03	478	1.19	515	1.59	97.04	1.22
Survey totals	15929	256.75	16490	1312.46	32419			1569.21
Total species	10		13		14			

Pacific rock crab (*Cancer antennarius*) dominated the catch, with 85.3% of the abundance and 49.4% of the biomass. The second and third most abundant species were also rock crabs, yellow rock crab (*Cancer anthonyi*) and graceful rock crab (*Cancer gracilis*), with 5.1% and 2.8% of the abundance, respectively. The species with the second greatest biomass (29.6%), purple jellyfish (*Pelagia colorata*), was fourth in abundance. Together with tuberculate pear crab (*Pyromaia tuberculata*), the top five abundant species accounted for over 97% of the individuals. Including

California spiny lobster (*Panulirus interruptus*), the three species with the greatest biomass accounted for over 90% of the total biomass.

Scattergood. Twenty-one motile macroinvertebrate species, comprised of 2,941 individuals with a biomass of 2,122.9 kg were collected during heat treatment surveys at Scattergood Generating Station (Table 14, Appendices H-14 and H-15). These species represented three phyla and 12 families, and included 16 species of arthropods (all crustaceans), three species of mollusks, and two species of echinoderms (Appendix H-1).

Table 14. Number of individuals and biomass (kg) of the five most abundant macroinvertebrate species impinged at Scattergood Generating Station. El Segundo and Scattergood Generating Stations NPDES, 2001.

Common Name	Abundance	Biomass	Percent		Cumulative Percent	
			Abundance	Biomass	Abundance	Biomass
red striped shrimp	824	671.37	28.02	31.63	28.02	31.63
yellow rock crab	730	312.62	24.82	14.73	52.84	46.35
graceful rock crab	535	105.92	18.19	4.99	71.03	51.34
intertidal coastal shrimp	218	277.63	7.41	13.08	78.44	64.42
California spiny lobster	205	30.95	6.97	1.46	85.41	65.88
Survey Totals	2941	2122.87				
Total Species	21					

The most abundant invertebrate species was red rock shrimp (*Lysmata californica*), which accounted for 28.0% of the overall abundance, and 31.6% of the biomass (Table 14, Appendices H-14 and H-15). The second and third most abundant species, yellow rock crab and graceful rock crab, contributed 24.8% and 18.2% to the abundance, respectively, and 14.7% and 5.0%, respectively, to the biomass. Together with intertidal coastal shrimp (*Heptacarpus palpator*) and California spiny lobster, the fourth and fifth most abundant species, the five most abundant species accounted for over 85% of the individuals, and almost 66% of the biomass.

Because of the sport and commercial importance of California spiny lobster, carapace lengths (CL) were measured to determine the size frequency of entrained individuals. This species was sufficiently abundant to construct a length-frequency histogram of catches from both El Segundo Generating Station and Scattergood Generating Station (Figure 15). Abundance of entrained and impinged California spiny lobster was greater at El Segundo Generating Station than at Scattergood Generating Station. At El Segundo Generating Station the distribution was bimodal, with peaks at 70 and 100 mm CL; Scattergood Generating Station had a single mode, with a peak at 70 mm CL. Legal size for commercial and sport take is 83 mm CL.

Figure 15. Length-frequency (carapace length) distribution of California spiny lobster (*Panulirus interruptus*) taken during impingement surveys. El Segundo and Scattergood Generating Stations NPDES, 2001.

DISCUSSION

WATER COLUMN MONITORING

In winter, inshore temperatures at the two stations closest to the discharges (RW2 and RW3) were nearly identical to temperatures at the upcoast and downcoast controls (Stations RW1 and RW4) on ebb tide and varied by less than 1°C on flood tide. On ebb tide, temperatures were generally higher at all stations probably due to solar insolation of the surface waters and there was a temperature differential of about 1.5°C at mid-depth downcoast Stations RW7 and RW8. In summer, surface temperatures were typically higher than in winter. Surface temperatures were similar between tides at all other stations. During the summer surveys, surface ambient temperature did not vary by more than 1°C on either tide throughout the study area. During both surveys, elevations of less than 1.5°C were noted between stations and tides in the study area. These were probably related to solar insolation. Thermal fields from generating station discharges were not detected at any stations during either survey. The greatest surface-to-bottom temperature differences were found at the 40-ft depth stations in winter and the deepest (offshore) stations in summer. All temperatures fell within ranges found in previous surveys (MBC 1990-2000).

The concentration of dissolved oxygen in seawater is affected by physical, chemical, and biological variables. High DO concentrations may result from cool water temperatures (solubility of oxygen in water increases as temperature decreases), active photosynthesis, and/or mixing at the air-water interface (Sverdrup et al. 1942). Conversely, low concentrations may result from warm water temperatures, high rates of organic decomposition, and/or extensive mixing of surface waters with oxygen-poor subsurface waters.

During the winter surveys, dissolved oxygen profiles were variable and corresponded to temperature profiles among stations and between tides. This direct correspondence of DO to temperature has been noted during previous sampling in the area (MBC 1997, 1999, 2000). Surface DO concentrations during the winter survey were, in general, about 0.5 mg/l higher than at the same stations during the summer survey. Dissolved oxygen concentrations generally increased with depth and a drop in temperature, as would be expected, during the winter survey. In summer, DO profiles varied for the first few meters and then were nearly vertical indicating very little mixing in the water column. All dissolved oxygen concentrations were well within the range of previously reported values (MBC 1990-2000). Dissolved oxygen concentrations in the study area appeared to be unaffected by the generating stations' discharges.

Hydrogen ion concentration (pH) varied only slightly with depth. Values were within ranges considered normal in the study area and were similar to values previously reported in the study area (MBC 1990-2000). In the open ocean, hydrogen ion concentration (pH) remains fairly constant due to the buffering capacity of seawater (Sverdrup et al. 1942). However, in nearshore areas, pH may be more variable due to physical, chemical, and biological influences. For instance, in areas with large organic influx, such as bays, estuaries, and river mouths, microbial decomposition is greater than in offshore areas. Along with a reduction in dissolved oxygen, decomposition also results in the production of humic acids, which decrease pH (Duxbury and Duxbury 1984). Reduced pH values may also occur in areas of freshwater influx, since freshwater usually has a lower pH than saltwater. In contrast, phytoplankton blooms, which are often associated with nearshore upwelling, may increase pH. High photosynthetic rates increase the removal of carbon dioxide from water, thus reducing the carbonic acid concentration and raising pH.

Salinity in the open ocean is generally 35 parts per thousand (ppt); that is, a 1,000-g sample of ocean water contains 35 g of dissolved compounds, collectively referred to as salts (Sverdrup et al. 1942). In nearshore areas subjected to freshwater influx, however, salinity is usually slightly lower. In southern California, salinity of nearshore waters is generally between 33 and 34 ppt (Dailey

et al. 1993). Reductions in nearshore salinity usually result from freshwater input, while slight increases are often associated with upwelling of colder, more saline bottom waters.

Salinity concentrations were slightly lower in winter than in summer (less than 0.5 ppt) and were nearly identical throughout the water column and the study area. Slight excursions were noted in summer at the surface at Station RW1 and at depth at Stations RW4, RW5, RW6, and RW8. It is probable that the later excursions are the result of differing water masses moving into the area as noted in the temperature profiles. The reason for the slight depression on flood tide at the surface at Station RW1 is unknown.

SEDIMENT MONITORING

Sediment Grain Size

In 2001, sediments were coarsest at Station B5, located upcoast of the Scattergood and El Segundo discharges on the 40-ft isobath, while finest sediments occurred at Stations B1 and B2, upcoast of the discharges at a depth of 20 ft. Mean particle size at Station B5 was five times (or greater) that at the other offshore stations. Mean grain size was the coarsest since 1990 due to the highly coarse sediments at Station B5 (Figure 16) (MBC 1990-1994, 1997-2000). Finest sediments have usually occurred at offshore Station B5, except in 1999 and the present study, when sediments at that station were much coarser than at all other stations. This year, the coarse sediments at Station B5 appeared to be relict red sand. Red sands were historically deposited at lower sea level stands, and represent ancient beaches or dunes that have been re-exposed by currents (Terry et al. 1956, Emery 1960). In Santa Monica Bay, these sands are found in a narrow band along the nearshore subtidal northwest of Palos Verdes Hills, in smaller nearshore patches stretching from El Segundo north past Marina del Rey, and further offshore just inside the shelf break (Emery 1960, MBC 2001). The sediments get their color from a thin stain of ferric oxide.

Figure 16. Comparison of sediment mean grain size, 1990 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

Percentage of silt at Station B2 in 2001 was the highest from any station in the last 10 years (Appendix D). Since 1990, highest silt percentages have generally occurred at Stations B2 and B5. Sediments in the study area are typically coarsest nearshore; greater turbulence and currents nearshore suspend finer particles which are deposited further offshore in calmer water. Sediment composition and distribution in the study area are likely primarily affected by natural causes, such as sediment transport, deposition from Ballona Creek, which enters Santa Monica Bay approximately two miles north of Station B1, and nearshore currents. Littoral currents in the study area move up to eight feet per second, and are capable of transporting beach sediments alongshore (Drake and Gorsline 1973). Dikes, groins, and jetties in the study area were constructed to facilitate sand accumulation; otherwise, beach sands tend to move toward Redondo Canyon and offshore

(MBC 1988). Results from the 2001 survey indicate no apparent patterns in sediment grain size relative to the discharges of the El Segundo and Scattergood Generating Stations.

Sediment Chemistry

Highest concentrations of chromium, copper, nickel, and zinc occurred at Stations B1 and B2 in 2001. Lowest concentrations of chromium, copper, and zinc were found at Station B3, and lowest nickel concentration was found at Station B5. Differences in metal concentrations among sites are often directly related to the amount of fine-grained material in the sediment. Fine-grained sediments may contain higher amounts of metals due to the greater available surface area (Ackermann 1980, de Groot et al. 1982). Therefore, comparisons should take into account the relative amounts of fine and coarse sediments.

Since 1990, highest metal levels have usually occurred at Stations B2 and B5, both upcoast from the El Segundo and Scattergood Generating Stations (Figure 17). From 1990 to 1993, percentages of fine sediments and metal levels were highest at Station B5. In 1993, the percentage of "fines" (silt and clay combined) increased at Station B2, and consequently the metal levels at Station B2 increased from among the lowest to levels typical at Station B5. In 1994, the highest percentage of fine sediments and, in general, the highest levels of metals were found at Station B2. To a lesser degree, percent fines and metals at Station B1, upcoast of Station B2, followed a similar pattern of increase from 1993 to 1997. In 1997, the highest percentage of fines and the corresponding comparatively high level of metals occurred at Station B5, but in 1998, 1999, and again in 2001, highest metal concentrations occurred at Station B2, the station with the largest amount of fine material. Similar concentrations of chromium were detected at Stations B1 and B2 in 2001; the second highest percentage of silt and clay was collected at Station B1 in 2001. Overall, sediment metal concentrations in 2001 were similar to values recorded in the study area since 1990 (MBC 1990-1994, 1997-2000).

All values observed in 2001 were within the range found in sediments within the Southern California Bight and were lower than or comparable to levels found by the National Oceanographic and Atmospheric Administration (NOAA) at other sandy, offshore sites in southern California (NOAA 1991a). Elevated sediment metal levels may be toxic to some organisms. Ranges of toxicity have been developed by NOAA (NOAA 1991b) and later updated (Long et al. 1995) using data from spiked sediment bioassays, sediment-water equilibrium partitioning, and the co-occurrence of adversely affected fauna and contaminant levels in the field. Chemical concentrations believed to be associated with adverse biological effects from the various independent studies were compared for each parameter. The lower 10 percentile was designated as the "Effects Range-Low" (ERL). The median of concentration levels was designated the "Effects Range-Median" (ERM). Since 1990, sediment metal concentrations in the study area have been well below the determined concentrations for low effects, which are 81 mg/kg for chromium, 34 mg/kg for copper, 20.9 mg/kg for nickel, and 150 mg/kg for zinc (Figure 17).

The wide distribution of metals in the study area does not appear to be related to the generating station discharges; more likely it is due to non-point source discharges, such as storm drains that carry street runoff into Santa Monica Bay (NOAA 1991c). Ballona Creek, to the north, could also be a source of fine sediments and their associated metal contaminants. There are several other potential sources of metals in the El Segundo area, as well, such as boating-related activities in Marina del Rey, nearby oil refineries, and the City of Los Angeles Hyperion Treatment Plant (MBC 1993b). The Hyperion Treatment Plant 5-mile discharge is 8,300 m from shore at a depth of 57 m. In 1997, City of Los Angeles Hyperion treatment plant discharged an estimated 0.65 metric tons (mt) of chromium, 17 mt of copper, 4.1 mt of nickel, and 20 mt of zinc into Santa Monica Bay (Raco-Rands and Steinberger 1998). These emissions represent between 1% and 19% of what was discharged 20 years earlier (in 1977) from the same outfall (Schafer 1978).

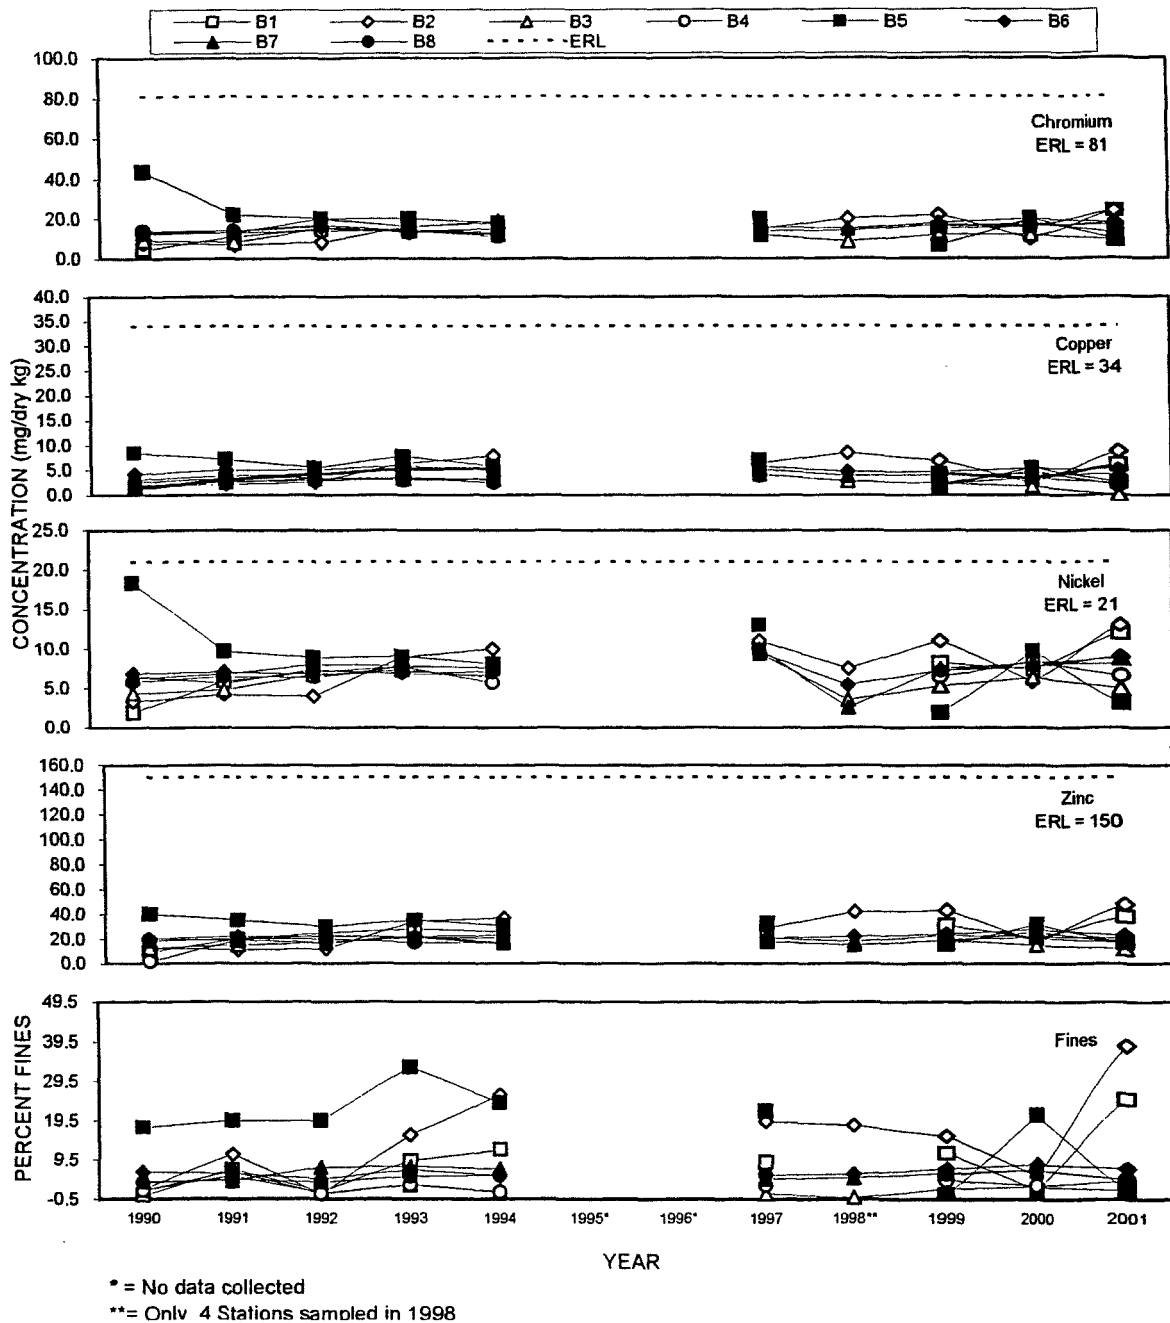

Figure 17. Comparison of sediment metal concentrations and percent fines by station, 1990 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

Concentrations of chromium, copper, nickel, and zinc in Santa Monica Bay as a whole are significantly higher than concentrations found in the Southern California Bight, even though the mean percent fines are similar (42.5% in the Bight versus 44.8% in Santa Monica Bay) (Schiff 1998). Results from the 1994 Southern California Bight Pilot Project indicate 50% of the area in Santa Monica Bay contained sediments with at least one constituent that exceeded the ERM. For comparison, only 7% of the area sampled outside the Bay contained sediment concentrations exceeding an ERM.

In 2001, little difference was seen between metal levels found at nearshore and offshore stations, and no extremely high or low values were noted in sediments at stations nearest the discharges. Highest metal concentrations occurred at Station B2, where the greatest amount of silt and clay occurred. As in past surveys, the distribution of metals in the study area appears to be related to localized sediment grain size. There is no indication that operation of the generating stations has had an appreciable effect on sediment metal concentrations in the study area.

MUSSEL BIOACCUMULATION

In 2001, bay mussels were collected from the study area for analysis of tissue metal concentrations.

Bay mussel tissue collected from the El Segundo 1&2 and 3&4 discharge structures in 2001 had detectable levels of copper and zinc. Mean copper concentration in 2001 from El Segundo was much lower than in 2000 and 1999. In 1999, copper concentration was highest of the six surveys performed since 1990 and three times higher than the mean concentration found in the 1994 study (Figure 18) (MBC 1990-1994, 1999). Mean zinc concentration in 2001 was also lower, about one-half the concentration noted in 1999, and similar to values recorded in 1992 and 1993. Chromium and nickel have not been detected in mussel tissue in the study area since the 1990 NPDES surveys.

Figure 18. Comparison of copper and zinc concentrations in bay mussel tissue at a pier reference site and at the west end of Catalina, 1990 - 1994 and 1999 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

Bay mussel tissue collected from the Scattergood discharge in 2001 also had detectable levels of copper and zinc. Mean copper concentration in 2001 was slightly higher than that noted at El Segundo, and was similar to the copper concentration detected in one replicate from Scattergood in 1999 (Figure 18) (MBC 1999). Mean zinc concentration in 2001 was considerably lower than zinc levels in 2000 and 1999 and was similar to concentrations noted at El Segundo in 2001. In 2001, copper and zinc concentrations in mussels collected from the two generating stations were similar to those from the Manhattan Pier reference site, but were well below levels found at the west end of Catalina Island reference site. In one replicate for copper from Scattergood, an anomalous

concentration of 87 mg/dry kg was reported; as the laboratory was unable to determine the validity of the reported concentration and it appears to be a decimal point error, it has been reported herein as 8.7 mg/dry kg. With the possible exception of the one copper replicate from Scattergood, none of the samples in 2001 were above the ERL levels reported for sediments. As ERL levels were derived for sediment metal levels, they are used herein for comparison purposes only.

In 1988, California State Mussel Watch (CSMW) found levels of copper between 16 and 23 mg/dry kg in resident California mussels (*Mytilus californianus*) collected in Santa Monica Bay (SWRCB 1990). The same study also found levels of copper between 3 and 29 mg/wet kg in transplanted California mussels collected in nearby Marina Del Rey. Mussel tissue analyzed from Ormond Beach in 1991 had a copper concentration of 55 mg/wet kg (Ogden 1991). An overview of copper concentrations in whole bay mussels conducted by CSMW and NOAA in the Southern California Bight from 1980 to 1986 found copper tissue levels ranging from 4.0 to 120 mg/dry kg (NOAA 1991c). One conclusion was that copper appeared to be a contaminant in mussels principally near major recreational and industrial harbors, and secondarily near smaller harbors.

In the same CSMW and NOAA studies, zinc concentrations ranged from 80 to 560 mg/dry kg. In 2001, maximum replicate zinc concentration in the study area was 84 mg/dry kg (from a replicate at El Segundo Generating Station). Highest mean zinc concentration of three replicates in the study area occurred in 1991 at 190 mg/dry kg, but levels have since remained lower (Figure 18).

Mussel tissue metal levels within ranges of those found in other studies indicate that there is no major source of metals in the study area. Copper levels in mussel tissue from Scattergood were higher in 1999, 2000, and 2001 than in previous surveys, but levels were lower than levels noted at the Catalina Island reference site and were similar to concentrations recorded in 2000 in the El Segundo discharge samples.

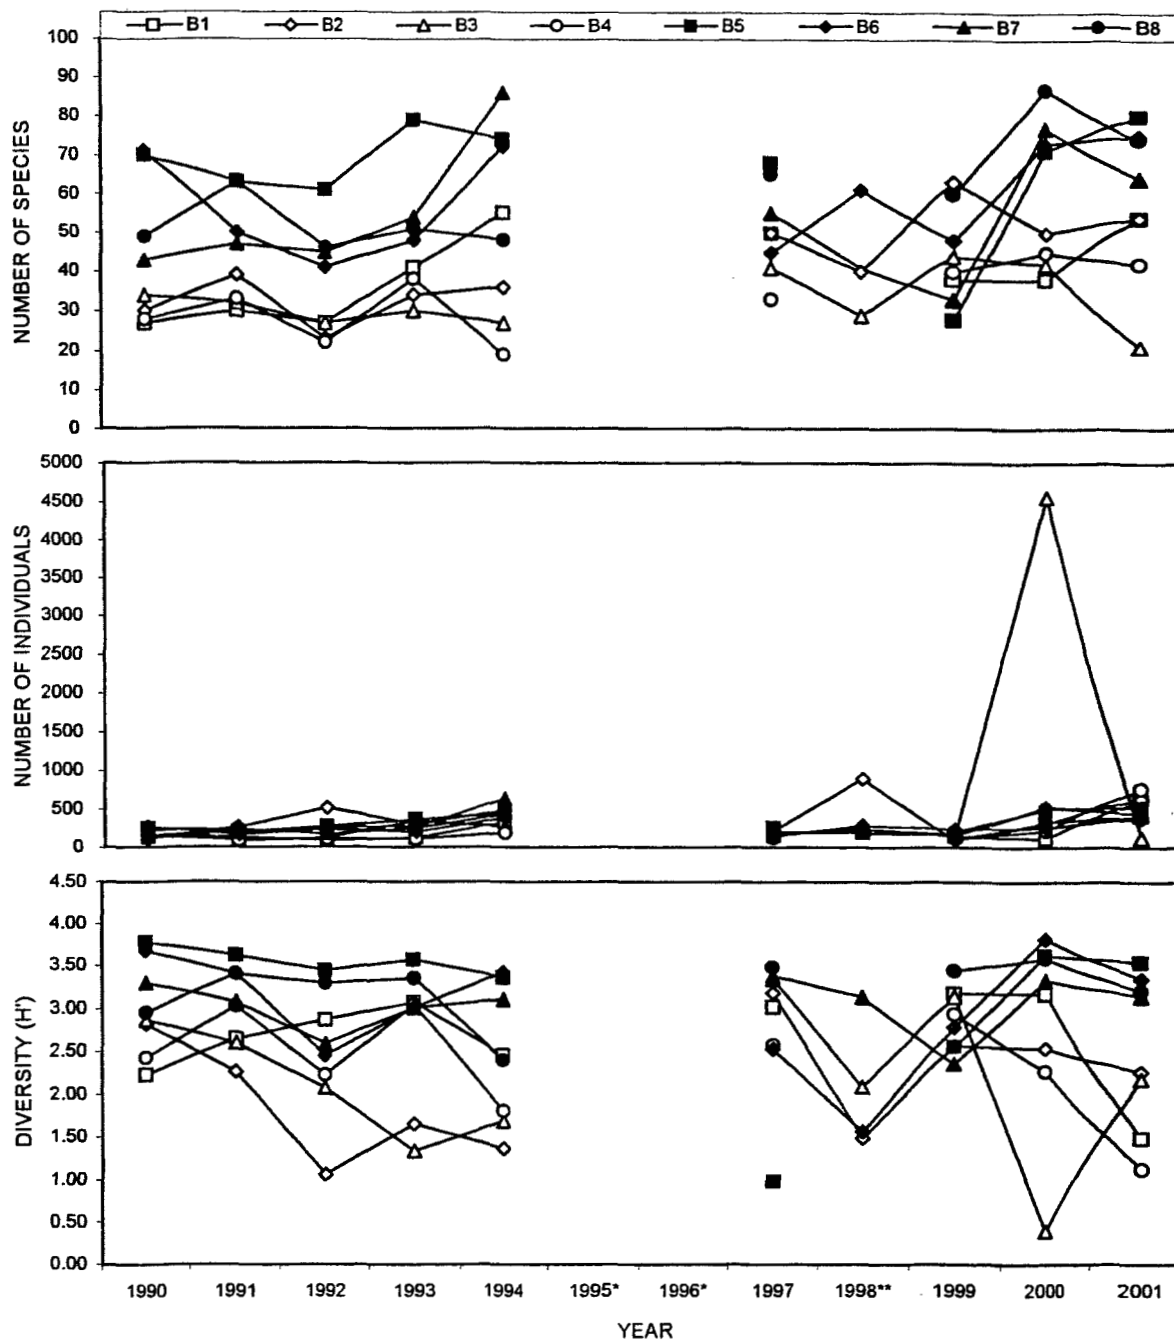

BIOLOGICAL MONITORING

Benthic Infauna

The benthic infauna offshore of the Scattergood and El Segundo Generating Stations was comprised primarily of annelid worms, small mollusks, and arthropods. More species occurred offshore than nearshore, with the highest number of species found furthest upcoast and offshore and the lowest number inshore and upcoast of the El Segundo Generating Station. Abundance was generally greater nearshore than offshore, with one notable exception: the number of individuals found immediately downcoast of the El Segundo Generating Station at Station B3 was about a quarter of the mean. This was probably related to the very low amount of silt and clay at that station; however, the highest abundance and species richness occurred at Station B5, an offshore station also with low amounts of silt and clay. At this station, sediments were composed of relict red sands which appear to have a completely different species composition as noted in the classification analysis which separated Station B5 into its own group because of this difference. Abundance did not necessarily correspond to species diversity as the highest and lowest abundances had the lowest species diversity indices. Species richness did correlate with species diversity.

The annelid worm *Apoprionospio pygmaea*, the most abundant species, was present in much greater abundance in the nearshore, whereas the amphipod *Diastylopsis tenuis* was more abundant by far at the two upcoast offshore stations. The other abundant species occurred primarily offshore.

Factors which contribute to infaunal community composition include habitat structure and food availability (Barnard 1963, Knox 1977). Habitat is partly determined by sediment characteristics, which in turn are controlled by disturbance, such as by water currents and wave action, which winnow away fine material. Sediment grain size influences the infauna through its

* = No data collected

** = Only 4 stations were sampled in 1998

Figure 19. Comparison of infaunal community parameters, 1990-2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

action, which winnow away fine material. Sediment grain size influences the infauna through its effect on stability and cohesiveness of the sediments, regulating the type of burrows these organisms build for protection and foraging (Posey 1985). Disturbance Hypothesis predicts that an area with a high amount of physical disturbance will support fewer species than one with a moderate amount of disturbance (Connell 1978). This is consistent with the findings in the study area, where

the nearshore environment is subject to stronger, more constant wave action than is the area offshore. Coarser sediments, such as occurred nearshore in 2001, generally contain less organic material than do finer sediments. This is also important for the majority of the species occurring in the study area which are deposit or filter feeders, gathering particulate organic matter through various means. The ability to swim and quickly reburrow into the substrate following wave disturbance is also critical, limiting the range of species that can tolerate the nearshore environment (Oliver et al. 1980).

Results of the 2001 survey indicate the same core group of species common to the inshore waters of the Southern California Bight continued to dominate the infauna offshore of El Segundo and Scattergood Generating Stations. Although community composition shifts in response to oceanographic perturbations, the community dominants remained very similar to those of previous NPDES summer surveys from 1990 through 1994 and 1997 and 2000 (MBC 1990-1994, 1997-2000). Most consistent has been *Apoprionospio pygmaea*, which has been among the most abundant species in the study area, and, in fact, was the most abundant species in six of 13 surveys since 1978 (LCMR/IRC 1979, IRC 1981; OC 1987, 1989; MBC 1990-1994, 1997-2000). *Diastylopsis tenuis* and *Tellina modesta* have also been abundant in almost every survey, although neither has been the most abundant species; Pacific sand dollar has been abundant in some years (most abundant species in 1986) but not in others. Several less abundant species (e.g., *Mediomastus acutus*, *Rhepoxynius menziesi*, *Spiophanes bombyx*) have been present consistently, contributing to the character of the community. Occasionally, however, a species not usually found among the core group has been very abundant, enough so at times as to be the most abundant species for a survey. Gould beancrabs, for example, were so abundant at one station as to be the most abundant species in 2000, but they have occurred only once before (in 1998), but even then they were not abundant. This species is known to experience increases and declines in its population. Gould beancrab occurs in dense aggregations on exposed sandy beaches and in the shallow subtidal habitat from Santa Cruz, California, to the southern end of the Baja California peninsula (Morris et al. 1980).

Like beancrabs, Pacific sand dollars also recruit in large numbers (Chia 1969; Merrill and Hobson 1970). They typically occur in dense but patchy aggregations just seaward of the breaker line to depths of 12 m. Adults orient themselves semi-vertically in the sediment, only partially buried, and feed on suspended material swept by on currents. They move shoreward during calm conditions and into deeper water when conditions are rough. Winter storms are occasionally severe enough to disrupt the sand dollar beds, after which the site is recolonized by juveniles recruited from other locations. Although studies have indicated that sediment grain size does not influence site selection by larval sand dollars (Timko 1975, Smith 1981), results of surveys offshore of Mandalay Beach suggest that sand dollars avoid fine sediments (MBC 1998b). Sand dollars occurred both nearshore and offshore in 2001, but few individuals occurred nearshore. Sand dollars were fourth in numerical dominance in 2001. Studies have shown that disturbance of infaunal communities by larger animals such as rays, crabs, and moon snails results in lower diversities, primarily from loss of tube-building polychaetes, particularly those in the family Spionidae (Virnstein 1977, Wiltse 1980). Sand dollars also appear to affect the infaunal community by disturbing the sediment as they position themselves on edge but also stabilizing the sediment through reducing erosion and providing protection from predators for other organisms (Merrill and Hobson 1970, Smith 1981). Intertidal sand dollar beds have been found to contain fewer species than the surrounding habitat, while subtidal beds showed no difference in species richness but did contain a slightly different community composition. In 2000, the most abundant polychaetes, *Apoprionospio pygmaea* and *Polydora cirrosa*, both spionids, were less abundant where large sand dollars were present than they were elsewhere. Large sand dollars occurred in the study area in 2000, 1999, and 1992, all occurrences were at nearshore stations (MBC 1992, 1999, 2000). In 1992, they were found at Station B2 where sediments were coarsest for that year. Species richness and diversity were low and the most abundant species at that station was the polychaete *Hesionura coineai difficilis*, a non-tubicolous, predatory species; another co-occurring, non-tubicolous polychaete, *Microphthalmus hystrix*, was also very abundant. Neither of these species

is normally highly abundant in the shallow subtidal environment. In 1999, sand dollars were found in large numbers at Station B3. Although they were smaller in size, on average, than in either 1992 or 2000, species richness and diversity were greater than the average for the survey. However, tubicolous polychaetes, such as *A. pygmaea*, were sparse.

In addition to infaunal community dominants, statistical parameters can also provide some comparison among survey years. In 2001, abundance and species richness were greater than the long-term means, while species richness was the greatest of any survey year (LCMR/IRC 1979, IRC 1981; OC 1987, 1989; MBC 1990-1994, 1997-2000). (Average station abundances were compared instead of survey totals, because the number of stations sampled has differed among years; see Table 21 in MBC 1990). Abundance in 2001 (486 individuals per station) was greater than any other year except 2000, where the unusual occurrence of Gould's bean clam almost doubled the previously high number in 1978 (416 individuals per station), which was followed closely by 1998 (402 individuals). The most abundant species in the 2001 survey was *A. pygmaea* (187 individuals per station, 39% of the individuals collected). Since 1990, as in 2001, species richness and diversity have been greater offshore than nearshore (Figure 19). Generally, abundance has been greater offshore also, but in 1992, 1998, and 2000, unusually high abundances of particular species nearshore (usually at only one station) have countered this trend.

The pattern of species distribution, abundance, richness, and diversity for the 2001 infaunal analyses appears to be the result of natural processes. The Scattergood and El Segundo Generating Stations' discharges do not appear to have adversely impacted the nearshore or offshore infaunal communities.

Impingement

Fish

Specifics of the individual generating stations are presented below, followed by information on common species taken at the two locations.

El Segundo. Three heat treatments and six normal operation surveys at Units 1 & 2, and four heat treatments and ten normal operation surveys at Units 3 & 4 were conducted from 1 October 2000 to 30 September 2001. During these surveys, 45 species, with an estimated abundance of 4,734 individuals weighing an estimated 637.1 kg were taken.

Of the total abundance, approximately 93% was taken during heat treatments, while slightly less than 7% was estimated to be taken during normal operations. Approximately 60% of the individuals were taken during heat treatments at Units 3 & 4; 58% of the individuals taken during the nine heat treatments were taken in two separate heat treatments in late spring and summer, one at each unit pair.

Fish impingement biomass data from El Segundo Generating Station Units 1 & 2 and Units 3 & 4 are available from 1979 to 2001 (Table 15). Impingement biomass for 2001 at El Segundo Generating Station was about one-half of its long-term mean. Fish biomass at El Segundo Generating Station during the period from 1979 to 1983 averaged 3,333 kg per year, but since 1984, it has remained relatively low, averaging only 723 kg per year. Beginning in 1984, fish biomass at El Segundo Generating Station has been in a two-to-five year cycle, with biomass ranging from around 200 to 750 kg per year, then peaking above 1,000 kg, then dropping the following year. The more than three-fold decrease in impingement since 1983 was likely due to the decreased demand for power from El Segundo Generating Station following completion of Units 2 & 3 at San Onofre Nuclear Generating Station (SONGS) in 1983-1984. With increased capacity at SONGS, many of the southern California generating stations (including El Segundo Generating Station) have operated at much lower capacity and, more importantly for fish impingement, with fewer circulators running,

twelve years. The next four highly ranked species (jacksnelt, walleye surfperch, kelp bass, and salem) ranked among the top ten in 10 of the 12 years (Table 16). All of the ten species with highest average rankings were present in 2001; four of those species were present in impingement samples in every year since 1990, with five present in 11 of the 12 years.

which resulted in decreased flows at the intake and a decline in impingement. In 2000 and 2001, the plant has operated at a higher percent capacity (with more flow) due to the increase in electricity demand. However, this alone is not the only factor influencing impingement losses, considering the 2.5-fold decrease in biomass and nearly 8-fold decrease in abundance between 2000 and 2001 (Appendix H-24); during 2000 the flow was 33.9% of total potential annual flow, while in 2001, it was 53.3%. During years of high abundance and biomass, the large change is usually a result of one or more pelagic schooling species occurring in one or two heat treatment surveys in high abundance. This is likely a result of chance encounters with the intake structure as these species pass nearby while foraging.

All species that occurred in impingement samples at El Segundo Generating Station were ranked for each of the last twelve years, and ranks were then averaged to determine the ten highest ranking species for the twelve-year period (Table 16). Only one of these species, queenfish, occurred among the ten highest rankings during every year over the last

Table 16. Ranking of the 10 most abundant fish species impinged during heat treatments at El Segundo Generating Station, 1990 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

Scattergood. Five heat treatments were conducted at Scattergood Generating Station from 1 October 2000 to 30 September 2001. During these surveys, 47 species, with an estimated abundance of 39,256 individuals weighing an estimated 2,122.9 kg were taken.

Abundance at Scattergood Generating Station in 2001 was dominated by two species, Pacific sardine and queenfish, which together constituted almost 78% of the overall abundance. While the queenfish were distributed relatively evenly throughout the year, the Pacific sardine were all taken during a single heat treatment in late fall.

Heat treatment data are available from Scattergood Generating Station from 1986 to 2001 (Table 15). Impingement biomass for 2001 at Scattergood Generating Station was slightly lower than its long-term mean. At Scattergood Generating Station fish biomass was lowest in 1992 and 1993. The following year, 1994, had the highest biomass of the 16 years, with similar peaks noted in 1996 and 2000. The low values coincide with the largest El Niño event recorded; the three high biomass years appear to be related to the chance increase in impingement of densely schooling pelagic species such as jack mackerel (*Trachurus symmetricus*) and jacksmelt in 1994, queenfish in 1996, and queenfish, jacksmelt, topsmelt, and Pacific sardine in 2001. Scattergood Generating Station delivers electricity into a separate power grid than El Segundo Generating Station, and was not affected by SONGS going online. From 1990 to 1995, during these large fluctuations in biomass, Scattergood Generating Station had an annual flow during each year at about 59% of the maximum design yearly flow.

All species that occurred in impingement samples at Scattergood Generating Station were ranked for each of the last twelve years and ranks were then averaged to determine the most abundant species for the twelve-year period (Table 17). Only two of these species, queenfish and topsmelt, occurred among the ten highest rankings during every year over the last twelve years. Of the other eight species, three (salema, barred sand bass, and walleye surfperch) were among the top ten during at least ten of the twelve years (Table 17). All of the ten species with highest average rankings were present in 2001, and all of these species were present in impingement samples in every year since 1990.

Table 17. Ranking of the 10 most abundant fish species impinged during heat treatments at Scattergood Generating Station, 1990 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

FO = frequency of occurrence

Of the most abundant species seen at the two generating stations in 2001, queenfish was the most abundant species at El Segundo, and second in abundance at Scattergood. It has been among the top five in abundance for the last eleven years, and is first in overall abundance since 1990 (Appendices H-24 and H-25). Queenfish are also among the most abundant fish caught in trawls in the nearshore Southern California Bight (MBC unpubl. trawl data). Queenfish is a schooling species abundant over sandy bottoms, and is most common at depths of 10 m (Allen 1982), which

coincides with the depth of the intake structures. They form quiescent schools near the bottom in daytime, and disperse and feed in the water column at night (Love 1996), when they become susceptible to the intake currents.

Pacific sardine was the most abundant species in 2001 at Scattergood Generating Station, but had low abundance at El Segundo Generating Station. Pacific sardines have made a remarkable comeback after a disastrous decline in the fisheries in the early 1950s. Although impingement catches were sporadically monitored in the 1960s and broad-scale monitoring commenced in the 1970s, it was not until 1993 and 1994 that large numbers of sardines appeared in the impingement catches at El Segundo Generating Station and Scattergood Generating Station. They have continued to be visitors offshore the power plants as evidenced by their regular impingement at the power plants since 1990 (MBC 1990-1994, 1997-2000). In overall abundance since 1990, they are third at El Segundo Generating Station and fourth at Scattergood Generating Station (Appendices H-24 and H-25); in averaged rankings they are among the top ten species since 1990 (Tables 16 and 17). This parallels their recent rise in abundance in California waters as their population expands (Love 1991).

Northern anchovy, the second most abundant species in 2001 at El Segundo Generating Station, was represented by very few individuals at Scattergood Generating Station. It is a schooling species which maintains tight schools during the day, feeding in the water column. It is common in the Southern California Bight and is one of the species most frequently captured in sampling conducted by otter trawls and other trawled gear, indicating that it is rather evenly distributed over the mainland shelf offshore of southern California. Northern anchovy is also an important component of the ecosystem in southern California. Anchovy eggs and larvae are prey for vertebrate and invertebrate planktivores (Leet et al. 1992). Juveniles in nearshore areas support a variety of predators, including birds and some recreational and commercially-important species of fish. Adults offshore are utilized by marine fishes, mammals, and birds. A correlation between breeding success of the endangered California brown pelican and anchovy abundance has been observed. Northern anchovy are also important commercially, for use in conversion to meal, oil, and protein products, and as live bait, with an approximate biomass of 646,000 tons in the central subpopulation, offshore of the southern California area (Leet et al. 1992). Northern anchovy is among the top seven dominant species at both generating stations since 1990 (Appendices H-24 and H-25).

Topsmelt and jacksmelt were the third and fourth most abundant species in 2001 at Scattergood Generating Station; at El Segundo Generating Station, jacksmelt was seventh most abundant, with topsmelt represented by very few individuals. In overall abundance, they were both among the top five species at Scattergood Generating Station, and among the top eleven species at El Segundo Generating Station, for the last eleven years (Appendices H-24 and H-25). Both species occur in great abundance in the inshore waters of Santa Monica Bay and are especially attracted to the discharge structures because of foraging opportunities (Stephens 1977). These two species are active during the day and quiescent at night; they have been observed in the impingement catch in great numbers immediately following tunnel reversal operations occurring during heat treatments conducted during daylight (Curtis, MBC, pers. obs.). Both species are frequently caught in the sportfishery, and are important prey items for several marine birds, but are seldom targeted by the commercial fish industry (Leet et al. 1992). Jacksmelt form larger, denser schools than topsmelt, and range over much of the inshore area of California (Leet et al. 1992).

Kelp bass and barred sand bass, the sixth most abundant species at El Segundo, and seventh most abundant species at Scattergood, respectively, are important sportfish and are of concern to the resource agencies charged with their management. Barred sand bass are found on the bottom near the margins of reefs to which they are attracted as focal points for feeding, mating, and living area (Helvey and Smith 1985). Although barred sand bass populations are probably equally abundant near the two generating stations areas, there are more focal points near the El Segundo plant. The preponderance of focal points surrounding the area of the El Segundo

Generating Station, such as the beach erosion groins, the Chevron discharge structure, and the two intake and discharge structures at El Segundo Generating Station, concentrates the population to the more risky areas near the intakes, resulting in greater takes at that station.

Kelp bass, on the other hand, are attracted to high-relief patch reefs, not as a focal point, but because prey availability is maximized at high current areas, such as at reefs (or artificial reefs such as the cooling water intakes and discharges). This species actively swims in the water column, maintaining positive rheotaxis to the current flow, a behavior which exposes a greater portion of the kelp bass population than that of other species to the intake flow. The disparity in catches between the two generating stations with regards to kelp bass impingement is again probably explained by the higher density of focal points (intake and discharge structures) near the El Segundo Generating Station.

Variations in the population sizes, oceanographic conditions, and the random nature of the schooling and foraging behavior of these species encountering the intake appears to determine the abundance and biomass of the catch seen at the two generating stations. With the intake structures of the two generating stations within approximately one-half mile of each other, large catches of one species at one generating station, and the near absence of that species at the other generating station during the same year, highlight this natural variability. At El Segundo Generating Station, at least 26 species, and at Scattergood Generating Station at least 45 species, have occurred in impingement sampling during nine of the last twelve years (Appendices H-24 and H-25). This recurring core group of species demonstrates the stability of the community and suggests that the populations present offshore are not unduly stressed by the relatively minor loss due to entrainment.

The histograms for queenfish, kelp bass, and barred sand bass were relatively smooth curves, indicating that the intake is not selective but it is impinging a cross section of the population found in the nearshore waters at El Segundo Generating Station and Scattergood Generating Station.

Length-frequency histograms of the queenfish population indicated similar populations impinged at both Scattergood Generating Station and at El Segundo Generating Station and in similar abundances. Slightly more smaller fish were taken at El Segundo Generating Station, giving a bimodal distribution, versus a unimodal distribution at Scattergood Generating Station. Queenfish were most abundant in the impingement catch at 130 mm SL, corresponding to individuals slightly over one year old (DeMartini and Fountain 1981). The second mode at 70 mm SL at El Segundo Generating Station corresponds to young-of-the-year indicating the presence of a successful spawn. Bimodal distributions, with peaks at similar sizes, have been seen during most of the prior surveys (MBC 1990-1994, 1997-2000).

The kelp bass population ranged from one- to fifteen-year-old fish (70 to 500 mm SL) (Hulbrook 1974, Love 1996). At Scattergood Generating Station, most of the fish were young-of-the-year to age-two, while at El Segundo Generating Station, the kelp bass distribution indicated most of the population age-four to age-six fish (220 to 290 mm). The kelp bass population distribution has been almost identical for the last nine years (MBC 1990-1994, 1997-2000).

The barred sand bass population ranged from young-of-the-year to eleven-year-old fish (50 to 430 mm SL) (Hulbrook 1974, Love 1996). At both generating stations, most of the fish were age-three to age-five (200 to 260 mm). The barred sand bass population distribution has been almost identical for the last six years (MBC 1990-1994, 1997-1998).

Macroinvertebrates

Macroinvertebrate species, abundance, and distribution at the two generating stations are presented in the following text.

El Segundo. Macroinvertebrate abundance at El Segundo Generating Station in 2001 was about three times the 10 year average, with biomass about twice the 10-year average (Table 18). Abundance was similar to that seen in 1999, while biomass was less than was taken in both 1999 and 2000 (Table 18). Most of the abundance and biomass during 1999 to 2001 was from estimated normal operations losses. Three rock crab species, purple jellyfish, and tuberculate pear crabs were the most abundant species, similar to prior surveys (MBC 1990-1994, 1997-2000), and contributed greatly to the biomass, with California spiny lobster and California two-spot octopus (*Octopus bimaculoides*) also high in biomass.

Table 18. Number of species, number of individuals, and biomass (kg) of macroinvertebrates impinged at El Segundo and Scattergood Generating Stations, 1990 - 2001. El Segundo and Scattergood Generating Stations NPDES, 2001.

	ESGS*			SGS		
	Number		Biomass	Number		Biomass

*1990-97 heat treatment data only; other years heat treatment and extrapolated normal operation combined data.

Scattergood. Macroinvertebrate abundance and biomass at Scattergood Generating Station in 2001 was slightly higher than the 10-year average (Table 18). Abundance was similar to that seen in 1998, while biomass was less than was taken in 2000 (Table 18). Three rock crab species, purple jellyfish, and tuberculate pear crabs were the most abundant species, similar to prior surveys (MBC 1990-1994, 1997-2000). Red-striped shrimp, two rock crab species, intertidal coastal shrimp and California spiny lobster accounted for most of the abundance, and the lobsters, California two-spot octopus, and three rock crab species comprised most of the biomass. These species are commonly among the most abundant species (MBC 1990-1994, 1997-2000)

Rock crabs are abundant at the generating station as larval stages are common in the plankton. These larval stages are entrained by the intake and many find the fouling community habitat growing on the intake and in the tunnels to there liking and settle therein. Typically, most of these larval stages do not survive to adulthood, but the availability of an unlimited food supply makes these intakes a superior habitat, until the next heat treatment. Jellyfish are common at certain times of the year in the inshore waters of the Southern California Bight; by chance, jellyfish encounter the intakes during passive drifting with ocean currents. Tuberculate pear crabs, and the shrimp and mollusk species seen, are common in the offshore sandy environment. Most of the individuals seen in the generating station are small in size, indicating that they are likely settling from the plankton in the intake conduits, and are removed in large numbers intermittently during plant operations. Some, such as California spiny lobster, are entrained irregularly as they forage near the intake structure.

Species diversity at both generating stations has remained similar since monitoring started, and abundance and biomass have fluctuated in a manner similar to that seen in the fish populations. Since the intake structure is providing habitat that would otherwise not be available, most of the individuals taken during impingement monitoring would most likely not have had adequate habitat to settle into, and therefore would have been lost to the offshore ecological environment. As

California spiny lobster are relatively large, they are removed from the intake water by the rakes and screens at the station. As most of these lobsters survive, they are physically removed by biologists and released back into the ocean unharmed. Therefore, the actual loss of the main commercial species, California spiny lobster, is minor compared to the amount removed by the commercial and sport industry, approximately 225,000 kg a year (Leet et al. 1992). Around 30% of the California spiny lobsters at each station were greater than the legal size limit (approximately 83 mm carapace length) (CDF&G 1997).

CONCLUSIONS

Water quality measurements in 2001 indicated that there was no detectable thermal elevation in the study area during either the winter or summer survey. Otherwise, only minor variations in temperature, DO, pH, and salinity were detected, all mostly due to temporal and spatial variations in upwelling of cold water and solar insolation to the surface waters. Water quality measurements indicated that the cooling water discharges from the El Segundo and Scattergood Generating Stations did not have an adverse effect on receiving waters in the study area.

Sediments in the study area were mostly sand, with a mean grain size in the fine sand category. Sediments were coarsest at offshore Station B5, upcoast of the Scattergood and El Segundo discharge structures, and finest at inshore Stations B1 and B2, also upcoast of the discharge structures. No spatial patterns were apparent that would suggest effects from the Scattergood or El Segundo Generating Stations. Natural causes, such as sediment deposition and transportation by nearshore currents, are likely responsible for interannual variation in sediment characteristics in the study area.

The distribution of metals in the sediments of the study area did not appear to be related to the generating station discharges in 2001. Highest concentrations of all metals were upcoast of the discharges and appear to be related to the amount of fine material in the sediments. Concentrations of all metals were within ranges typically found in sediments in the Southern California Bight and below levels determined to be potentially toxic to benthic organisms.

In 2001, mean copper and zinc concentrations from mussel tissue collected near the Scattergood Generating Station were similar to values recorded in 1999 and in 2000. At El Segundo, zinc and copper concentrations were similar to or lower than values recorded since 1990. All metal concentrations were within ranges found in other surveys in the Southern California Bight. Since 1990, chromium and nickel have not been detected in mussel tissues near the generating stations. These results indicate that the bioaccumulation of metals has not been appreciable near the El Segundo and Scattergood Generating Station discharges.

The benthic infaunal community in the study area in 2001 was similar to that of previous years and overall abundance and species richness were higher than the long term means and second highest recorded for the study area. Sediment characteristics appeared to influence the infaunal community, with greater abundance and species richness occurring offshore where sediments were finer and more poorly sorted. No pattern in species composition or abundance could be attributed to the Scattergood and El Segundo Generating Stations' discharges.

High diversity of the fish population entrained by the El Segundo and Scattergood Generating Stations' intakes suggest that a variety of niches are available in the area of the discharge and intake structures. High abundances are related to increased plant operations. Still, continued high diversity and abundance of core species, as evidenced by impingement data from the last eleven years, indicated that impingement at the El Segundo and Scattergood and Generating Stations is not unduly influencing the fish and macroinvertebrate communities in the nearshore.

The overall results of the 2001 NPDES monitoring program indicated that operation of the El Segundo and Scattergood Generating Stations had no detectable effects on the beneficial uses of the receiving waters.

B. Receiving Water Monitoring

The receiving water monitoring program shall consist of periodic biological surveys of the area surrounding the discharge, and shall include studies of those physical and chemical characteristics of the receiving waters which may be impacted by the discharge.

This program may be performed as a joint effort with the City of Los Angeles' Department of Water and Power in connection with the receiving water monitoring program for the Scattergood Generating Station.

Location of Sampling Stations (see Attached Figure 3):

1. Receiving water stations shall be located as follows:
 - a. RW1 - 7,875 feet upcoast of the Scattergood discharge terminus, at a depth of 20 feet.
 - b. RW2 - 1,000 feet upcoast of the Scattergood discharge terminus, at a depth of 20.
 - c. RW3 - 1,750 feet downcoast of the El Segundo discharge terminus, at a depth of 20 feet.
 - d. RW4 - 9,900 feet downcoast of the El Segundo discharge terminus, at a depth of 20 feet.
 - e. RW5 - directly offshore of Station RW1, at a depth of 40 feet.
 - f. RW6 - directly offshore of Station RW2, at a depth of 40 feet.
 - g. RW7 - directly offshore of station RW3, at a depth of 40 feet.
 - h. RW8 - directly offshore of Station RW4, at a depth of 40 feet.
 - i. RW9 - directly offshore of Station RW1, at a depth of 60 feet.
 - j. RW10 - directly offshore of Station RW2, at a depth of 60 feet.

- k. RW11 - directly offshore of Station RW3, at a depth of 60 feet.
- l. RW12 - directly offshore of Station RW4, at a depth of 60 feet.

2. Benthic stations shall be located as follows:

Stations B1 through B8 shall be located directly beneath Stations RW1 through RW8, respectively.

C. Type and Frequency of Sampling:

1. Temperature profiles shall be measured semi-annually (summer and winter) each year at Stations RW1 through RW12 from surface to bottom at a minimum of one meter intervals. Dissolved oxygen levels and pH shall be measured semi-annually at the surface, mid-depth and bottom at each station, at a minimum. All stations shall be sampled on both a flooding tide and an ebbing tide during each semi-annual survey.
2. Impingement sampling for fish and commercially important macroinvertebrates shall be conducted at least once every two months at intake Nos. 001 and 002. Impingement sampling shall coincide with heat treatments.

Fish and macroinvertebrates shall be identified to the lowest possible taxon. For each intake point, data reported shall include numerical abundance of each fish and macroinvertebrate species, wet weight of each species (when combined weight of individuals in each species exceeds 0.2 kg), number of individuals in each 1-centimeter size class (based on standard length) for each species and total number of species are collected. When large numbers of given species are collected, length/weight data need only be recorded for 50 individuals and total number and total weight may be estimated based on aliquots samples. Total fish impinged per heat treatment or sampling event shall be reported and data shall be expressed per unit volume water entrained.

3. Native California mussels (*Mytilus Californianus*) shall be collected during the summer from the discharge conduit, as close to the point of discharge as possible, for bioaccumulation monitoring. The mussels shall be collected and analyzed as described in Appendix A of the "California State Mussel Watch Marine Water Quality Monitoring Program 1985-86" (Water Quality Monitoring Report No. 87-2WQ). Mussel tissue shall be analyzed for copper, chromium, nickel, and zinc at a minimum.

Monitoring and Reporting Program No. CI- 4667

Order No. 00-084
CA0001147

4. Benthic sampling shall be conducted annually during the summer at Stations B1 through B8.
 - a. One liter sediment core samples shall be collected by divers at each of the benthic stations for biological examination and determination of biomass and diversity, and for sediment analyses. Four replicates shall be obtained at each station for benthic analyses, and each shall be analyzed separately. A fifth sample shall be taken at each station for sediment analyses and general description.
 - b. Each benthic replicate sample shall be sieved through a 0.5 mm standard mesh screen. All organisms recovered shall be enumerated and identified to the lowest taxon possible. Infaunal organisms shall be reported as concentrations per liter for each replicate and each station. Total abundance, number of species and Shannon-Weiner diversity indices shall be calculated (using natural logs) for each replicate and each station.

Biomass shall be determined as the wet weight in grams or milligrams retained on a 0.5 millimeter screen per unit volume (e.g., 1 liter) of sediment. Biomass shall be reported for each major taxonomic group (e.g., polychaetes, crustaceans, mollusks) for each replicate and each station.
 - c. Sediment grain size analyses shall be performed on each sediment sample (sufficiently detailed to calculate percent weight in relation to phi size). Sub samples (upper two centimeters) shall be taken from each sediment sample and analyzed for copper, chromium, nickel and zinc.
5. The following general observations or measurements at the receiving water and benthic stations shall be reported.
 - a. Tidal stage and time of monitoring.
 - b. General water conditions.
 - c. Extent of visible turbidity or color patches.
 - d. Appearance of oil films or grease, or floatable material.
 - e. Depth at each station for each sampling period.
 - f. Presence or absence of red tide.

Monitoring and Reporting Program No. CI- 4667

Order No. 00-084
CA0001147

- g. Presence of marine life.
 - h. Presence and activity of the California least tern and the California brown pelican.
6. During the discharge of calcareous material (excluding heat treatment discharge) to the receiving waters, the following observations or measurements shall be recorded and reported in the next monitoring report:
- a. Date and times of discharge(s).
 - b. Estimate of volume and weight of discharge(s).
 - c. Composition of discharge(s).
 - d. General water conditions and weather conditions.
 - e. Appearance and extent of any oil films or grease, floatable material or odors.
 - f. Appearance and extent of visible turbidity or color patches.
 - g. Presence of marine life.
 - h. Presence and activity of the California least tern and the California brown pelican.

SUMMARY OF RECEIVING WATER MONITORING

<u>Constituent</u>	<u>Units</u>	<u>Station No.</u>	<u>Type of Sample</u>	<u>Minimum Frequency of Analysis</u>
Temperature	°C	RW1-RW12	vertical profile	semi-annually (flood, ebb)
Dissolved oxygen	mg/L	RW1-RW12	vertical profile	semi-annually (flood, ebb)
pH	pH units	RW1-RW12	vertical profile	semi-annually (flood, ebb)
Fish and macro invertebrates	---	intakes No. 001 and 002	impingement	bimonthly
Mussels	---	Discharge	tissue	annually
Benthic infauna	---	B1-B8	grab	annually
Sediments	---	B1-B8	grab	annually

The receiving water monitoring report containing the results of semiannual and annual monitoring shall be received at the Regional Board on March 1 of each year following the calendar year of data collection.

V. STORMWATER MONITORING PROGRAM

The discharger shall implement the Monitoring and Reporting Requirements for individual dischargers contained in the general permit for Dischargers of Storm Water Associated with Industrial Activities (State Board Order No. 97-030-DWQ adopted on April 17, 1997). The monitoring reports shall be received at the Regional Board by July 1 of each year. Indicate in the report the Compliance File CI-4667.

B. Receiving Water Monitoring

The receiving water monitoring program shall consist of periodic biological surveys of the area surrounding the discharge, and shall include studies of those physical and chemical characteristics of the receiving waters which may be impacted by the discharge.

This program may be performed as a joint effort with El Segundo Power, LLC, in connection with the receiving water monitoring program for the El Segundo Generating Station.

Location of Sampling Stations (see Attached Figure 3)

1. Receiving water stations shall be located as follows

- a. RW1 - 7,875 feet upcoast of the Scattergood discharge terminus, at a depth of 20 feet.
- b. RW2 - 1,000 feet upcoast of the Scattergood discharge terminus, at a depth of 20.
- c. RW3 - 1,750 feet downcoast of the El Segundo discharge terminus, at a depth of 20 feet.
- d. RW4 - 9,900 feet downcoast of the El Segundo discharge terminus, at a depth of 20 feet.
- e. RW5 - directly offshore of Station RW1, at a depth of 40 feet.
- f. RW6 - directly offshore of Station RW2, at a depth of 40 feet.
- g. RW7 - directly offshore of station RW3, at a depth of 40 feet.
- h. RW8 - directly offshore of Station RW4, at a depth of 40 feet.
- i. RW9 - directly offshore of Station RW1, at a depth of 60 feet.
- j. RW10 - directly offshore of Station RW2, at a depth of 60 feet.
- k. RW11 - directly offshore of Station RW3, at a depth of 60 feet.

APPENDIX B

Grain size techniques

Appendix B. Grain size techniques.

Sediment Grain Size Analysis

Analysis of sediment samples for size distribution characteristics are performed using two techniques. Sediments in the gravel size range (> 2.0 mm in diameter) are analyzed using a series of standard sieves having screen openings of 0.5 phi increments (diameter in phi units = $-\log_2$ diameter in mm, or $= -\ln$ diameter in mm $\div \ln 2$). The sand-silt-clay fraction of sediments [-1 phi through 4 phi (2.0 mm through 0.0625 mm) for sand], [4 phi through 8 phi (0.0625 mm through 0.004 mm) for silt, 8 phi and greater for clay (0.0039 mm and smaller)] is analyzed by laser light diffraction. The sample is suspended in a suspension column and continuously circulated through the laser beam. The laser beam passes through the sample where the suspended particles scatter incident light. Fourier optics collect diffracted light and focus it on to three sets of detectors. A composite, time-averaged diffraction pattern is measured by 126 detectors. Sizes are computed and summed into normal distribution classifications.

Laboratory data from the two methods are mathematically combined and entered into a computer program which calculates and prints size-distribution characteristics and plots both interval and cumulative frequency distribution curves.

Analysis of the plotted cumulative size frequency curves is performed as described by Inman (1952). The median, 5th, 16th, 84th, and 95th percentiles (converted to phi notation) of the sediment distribution curve is used to calculate mean grain size diameter, sorting coefficient, and measures of skewness and kurtosis. Where sediment distribution coincides with a normal distribution curve, the 16th and 84th percentiles represent diameters one standard deviation on either side of the mean. The following formulas are used in the calculations:

1. Mean Diameter (M_ϕ) is the average particle size in the central 68% of the distribution.

$$M_\phi = (\phi_{16} + \phi_{50} + \phi_{84}) / 3$$

2. Sorting (σ_ϕ) measures the uniformity (or non-uniformity) of particle quantities in each size category of the sediment distribution. A σ_ϕ value under 0.35phi indicates that particles are very well sorted (i.e. sediments are primarily composed of a narrow range of size classes, or a single size class), while a value of over 4.0phi indicates that the sediments are extremely poorly sorted, or evenly distributed among size classes.

$$\sigma_\phi = \frac{\phi_{84} - \phi_{16}}{4} + \frac{\phi_{95} - \phi_5}{6.6}$$

3. Skewness (α_ϕ) is a measure of the direction and extent of departure of the mean from the median (in a normal or symmetrical curve they coincide). In symmetrical curves, $\alpha_\phi=0.00$ with limits of -1.00 and +1.00. Negative values indicate the particle distribution is skewed toward larger particle diameters, while positive values indicate the distribution is skewed toward smaller particle diameters.

$$\alpha_\phi = \frac{\phi_{16} + \phi_{84} - 2\phi_{50}}{2(\phi_{84} - \phi_{16})} + \frac{\phi_5 + \phi_{95} - 2\phi_{50}}{2(\phi_{95} - \phi_5)}$$

4. Kurtosis (β_ϕ) is a measure of how far the sediment distribution curve departs from a normal Gaussian shape at its peak. Curves with greater than normal amounts of sediment at their modes will be sharp or leptokurtic ($\beta_\phi > 1$). Those with fatter tails and lower peaks than expected are termed platykurtic ($\beta_\phi < 1$). $\beta_\phi = 1.00$ for a normal curve. Curve category interpretations are based on Folk (1974).

$$\beta_\phi = \frac{\phi_{95} - \phi_5}{2.44(\phi_{75} - \phi_{25})}$$

Phi - Millimeter Conversion Figure

Measurement sorting values for a large number of sediments has suggested the following verbal classification scale for sorting:

σ_1 under .35 ϕ ,	very well sorted	1.0-2.0 ϕ ,	poorly sorted
.35-.50 ϕ ,	well sorted	2.0-4.0 ϕ ,	very poorly sorted
.50-.71 ϕ ,	moderately well sorted	over 4.0 ϕ ,	extremely poorly sorted
.71-1.0 ϕ	moderately sorted

Sampled: 08/10/01
Received: 08/14/01

DATA QUALIFIERS AND DEFINITIONS

- M-HA** Due to high levels of analyte in the sample, the MS/MSD calculation does not provide useful spike recovery information. See Blank Spike (LCS).
- M1** The MS and/or MSD were above the acceptance limits due to sample matrix interference. See Blank Spike (LCS).
- R** The RPD exceeded the method control limit due to sample matrix effects. The individual analyte QA/QC recoveries, however, were within acceptance limits.
- ND** Analyte NOT DETECTED at or above the reporting limit or MDL, if MDL is specified.
- NR** Not reported.
- RPD** Relative Percent Difference

DATA QUALIFIERS AND DEFINITIONS

- H3** Sample was received and analyzed past holding time.
M2 The MS and/or MSD were below the acceptance limits due to sample matrix interference. See Blank Spike (LCS).
R-3 The RPD exceeded the method control limit due to sample matrix effects.
ND Analyte NOT DETECTED at or above the reporting limit or MDL, if MDL is specified.
NR Not reported.
RPD Relative Percent Difference

SCAMIT = Southern California Association of Marine Invertebrate Taxonomists

The following footnotes indicate names used in previous surveys:

- Edwardsia* sp G of MEC, of Ljubenkov
- Platyhelminthes* sp D of MBC
- Tubulanus* sp or *T. pellucidus/polymorphus*
- Paranemertes* sp A SCAMIT
- Mysella* sp A of SCAMIT
- Mysella tumida*
- Crepidula excavata*
- Nitidiscala sawinae*
- Turbonilla* sp E of MBC
- Aphelochaeta* sp C Dorsey, *Tharyx* sp C SCAMIT, or *Tharyx* spp (in part)
- Apoprionospio pygmaeus* or *Prionospio pygmaeus*
- Acmira catherinae* or *Acesta catherinae*
- Chaetozona "setosa"*, C. cf. *Setosa*, or *C. setosa*
- Polydora socialis*
- Glycera covoluta*
- Glycera capitata*
- Haploscoloplos elongata*
- Mediomastus ambiseta*, M. *acutus*, or M. *californiensis*
- Monticellina dorsobranchialis*, *Tharyx* sp A SCAMIT, or *Tharyx* spp (in part)
- Nephtys cornuta franciscana*
- Owenia collaris*
- Pectinaria californiensis newportensis*
- Gyptis brevipalpa*
- Minuspia cirrifer*, *Prionospio cirrifer*, or *P. lighti*
- Prionospio* sp A of SCAMIT
- Scoloplos armiger* or *Scoloplos "armiger"*
- Thalassessa spinosa* or *Eusigalion spinosa*
- Spiophanes missionensis*
- Synchelidium rectipalatum*
- Synchelidium shoemakeri*
- Campylaspis* sp C MBC
- Cumella* sp A of Myers & Benedict
- Edotea sublittoralis*
- Megaluropus longimerus*
- Monoculodes hartmanae*
- Metaceradocus occidentalis*
- Jassa falcata*
- Nebalia* sp A SCAMIT 1995
- Callianassa* sp or *Callianassa californiensis*
- Photis* OC1 (MEC) 1996
- Paraphoxus epistomus* or *Rhepoxynius epistomus*
- Munna* sp
- Leptosynapta* sp B of Benedict, L. sp B of MBC
- Hemichordata or Hemichordata, unid.

APPENDIX H

Fish and macroinvertebrate heat treatment and normal operation data

Appendix H-1. Fish and macroinvertebrate heat treatment master species list. El Segundo and Scattergood Generating Stations NPDES, 2001.

PHYLUM Class	Family	Species	Common Name	PHYLUM Class	Family	Species	Common Name
CNIDARIA				VERTEBRATA cont'd.			
Scyphozoa				Ophidiidae			
Pelagiidae				<i>Ophidion scrippsae</i>			basketweave cusk-eel
<i>Pelagia colorata</i>			purple jellyfish	Batrachoididae			
				<i>Porichthys myriaster</i>			specklefin midshipman
				<i>Porichthys notatus</i>			plainfin midshipman
MOLLUSCA				Atherinidae			
Gastropoda				<i>Atherinops affinis</i>			topsmelt
Aglaidae				<i>Atherinopsis californiensis</i>			jacksmelt
<i>Navanax inermis</i>			navanax	<i>Leuresthes tenuis</i>			California grunion
Cardiidae				Scorpaenidae			
<i>Laevicardium substriatum</i>			egg cockle	<i>Scorpaena guttata</i>			California scorpionfish
Cephalopoda				<i>Sebastes auriculatus</i>			brown rockfish
Octopodidae				<i>Sebastes rastrelliger</i>			grass rockfish
<i>Octopus bimaculoides</i>			California two-spot octopus	Hexagrammidae			
ARTHROPODA				<i>Oxylebius pictus</i>			painted greenling
Malacostraca				Cottidae			
Hippolytidae				<i>Ruscarius creaseri</i>			roughneck sculpin
<i>Heptacarpus palpator</i>			intertidal coastal (=tiger) shrimp	<i>Scorpaenichthys marmoratus</i>			cabezon
<i>Lysmata californica</i>			red rock (= red striped) shrimp	Serranidae			
Palinuridae				<i>Paralabrax clathratus</i>			kelp bass
<i>Panulirus interruptus</i>			California spiny lobster	<i>Paralabrax nebulifer</i>			barred sand bass
Majidae				Carangidae			
<i>Loxorhynchus crispatus</i>			masking crab	<i>Trachurus symmetricus</i>			jack mackerel
<i>Loxorhynchus grandis</i>			sheep crab	Haemulidae (=Pomadasyidae)			
<i>Pugettia producta</i>			northern kelp crab	<i>Anisotremus davidsonii</i>			sargo
<i>Pyromaia tuberculata</i>			tuberculate pear crab	<i>Xenistius californiensis</i>			salema
<i>Scyra acutifrons</i>			sharpnose crab	Sciaenidae			
Cancridae				<i>Atractoscion nobilis</i>			white seabass
<i>Cancer amphioetus</i>			bigtooth rock crab	<i>Cheilotrema saturnum</i>			black croaker
<i>Cancer antennarius</i>			Pacific rock crab	<i>Genyonemus lineatus</i>			white croaker
<i>Cancer anthonyi</i>			yellow rock crab	<i>Menticirrhus undulatus</i>			California corbina
<i>Cancer gracilis</i>			graceful rock crab	<i>Seriphus politus</i>			queenfish
Portunidae				<i>Umbrina roncadore</i>			yellowfin croaker
<i>Portunus xantusii</i>			Xantus swimming crab	Kyphosidae (includes Girellidae and Scorpidae)			
Xanthidae				<i>Girella nigricans</i>			opaleye
<i>Pilumnus spinohirsutus</i>			retiring hairy crab	<i>Hermosilla azurea</i>			zebra perch
Grapsidae				<i>Medialuna californiensis</i>			halfmoon
<i>Hemigrapsus nudus</i>			purple shore crab	Embiotocidae			
<i>Pachygrapsus crassipes</i>			striped shore crab	<i>Cymatogaster aggregata</i>			shiner perch
ECHINODERMATA				<i>Embiotoca jacksoni</i>			black perch
Asteroidea				<i>Hyperprosopon argenteum</i>			walleye surfperch
Asteriidae				<i>Phanerodon furcatus</i>			white seaperch
<i>Pisaster ochraceus</i>			ochre starfish	<i>Rhacochilus toxotes</i>			rubberlip seaperch
Holothuroidea				<i>Rhacochilus vacca</i>			pile perch
Stichopodidae				Pomacentridae			
<i>Parastichopus parvimensis</i>			warty sea cucumber	<i>Chromis punctipinnis</i>			blacksmith
<i>Parastichopus sp</i>			sea cucumber	<i>Hypsypops rubicundus</i>			garibaldi
VERTEBRATA				Sphyraenidae			
Elasmobranchiomorphi (= Chondrichthyes, Elasmobranchii)				<i>Sphyraena argentea</i>			California barracuda
Heterodontidae				Labridae			
<i>Heterodontus francisci</i>			horn shark	<i>Halichoeres semicinctus</i>			rock wrasse
Scyliorhinidae				<i>Oxyjulis californica</i>			senorita
<i>Cephaloscyllium ventriosum</i>			swell shark	<i>Semicossyphus pulcher</i>			California sheephead
Carcharinidae				Clinidae			
<i>Mustelus californicus</i>			gray smoothhound	<i>Heterostichus rostratus</i>			giant kelpfish
Rhinobatidae				Blennidae			
<i>Platyrrhinoidis triseriata</i>			thornback	<i>Hypsoblennius gilberti</i>			rockpool blenny
<i>Rhinobatos productus</i>			shovelnose guitarfish	Scombridae			
Myliobatidae				<i>Scomber japonicus</i>			chub mackerel
<i>Myliobatis californica</i>			bat ray	Stromateidae			
Urolophidae (Dasyatidae, in part)				<i>Peprilus similimus</i>			Pacific pompano
<i>Urolophus halleri</i>			round stingray	Bothidae (=Paralichthyidae)			
Osteichthyes (=Actinopterygii)				<i>Citharichthys stigmæus</i>			speckled sanddab
Clupeidae				<i>Paralichthys californicus</i>			California halibut
<i>Sardinops sagax</i>			Pacific sardine	Pleuronectidae			
Engraulidae				<i>Hypsopsetta guttulata</i>			diamond turbot
<i>Anchoa compressa</i>			deepbody anchovy	<i>Pleuronichthys ritteri</i>			spotted turbot
<i>Engraulis mordax</i>			northern anchovy	Balistidae			
				<i>Balistes polylepis</i>			finescale triggerfish

Appendix H-2. Abundance, biomass (kg), and percent occurrence of fish impinged at El Segundo Generating Station Units 1 & 2 and 3 & 4. El Segundo and Scattergood Generating Stations NPDES, 2001.

Species	Units 1 & 2		Units 3 & 4		Total		% Comp.	
	Abundance	Biomass	Abundance	Biomass	Abundance	Biomass	Abundance	Biomass
<i>Seriphus politus</i>	495	18.633	1512	41.886	2007	60.519	42.40	9.50
